

# ON SIMPSON MODULI SPACES OF STABLE SHEAVES ON $\mathbb{P}_2$ WITH LINEAR HILBERT POLYNOMIAL

HANS GEORG FREIERMUTH

*Preprint – Universität Kaiserslautern*

ABSTRACT. In this short note we prove some general results on semi-stable sheaves on  $\mathbb{P}_2$  and  $\mathbb{P}_3$  with arbitrary linear Hilbert polynomial. Using Beilinson's spectral sequence, we compute free resolutions for this class of semi-stable sheaves and deduce that if  $\mu$  and  $\chi$  are coprime the smooth moduli spaces  $M_{\mu m + \chi}(\mathbb{P}_2)$  and  $M_{\mu m + (\mu - \chi)}(\mathbb{P}_2)$  are birationally equivalent.

## 1. INTRODUCTION

Moduli of torsionfree semi-stable sheaves on  $\mathbb{P}_2$  and  $\mathbb{P}_3$  with fixed Hilbert polynomial were introduced by Maruyama and others. They have been intensively studied during the last decades. In 1994, Simpson [9] showed that the family of *arbitrary* semi-stable sheaves with fixed Hilbert Polynomial  $P$  on a smooth projective variety  $X$  is bounded. Using this, he proved the existence of a projective scheme  $M_P(X)$  corepresenting the moduli functor  $\mathcal{M}_P(X)(S)$  of  $S$ -flat coherent sheaves over  $X \times S$  with semi-stable fibers  $\mathcal{F}_s$  and  $P_{\mathcal{F}_s} = P$ . For  $\dim(X) \geq 2$  and linear Hilbert polynomial  $P(m) = \mu m + \chi$ , it is if all the sheaves in  $M_P(X)$  have torsion and are supported on degree  $\mu$  curves, there is not much known about these spaces.

LePotier [7] proved that the coarse moduli spaces  $M_{\mu m + \chi}(\mathbb{P}_2)$  are irreducible, locally factorial projective varieties of dimension  $\mu^2 + 1$ . They are rational at least if  $\chi \equiv \pm 1 \pmod{\mu}$ ,  $\chi \equiv \pm 2 \pmod{\mu}$  and for small multiplicities  $\mu \leq 4$ .

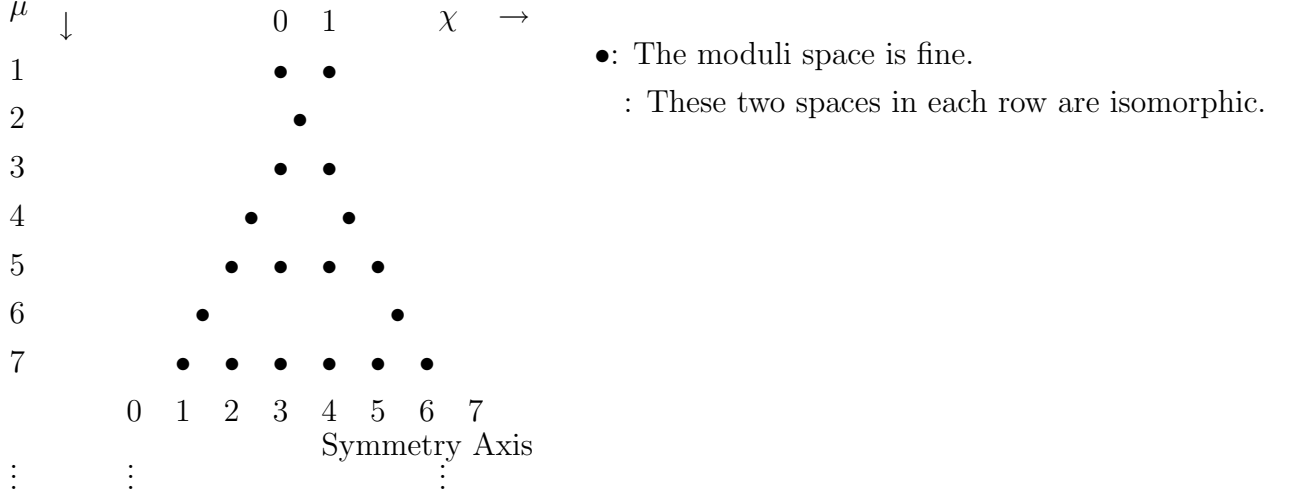

Furthermore, he described for  $\mu \leq 4$  the geometrical properties of  $M_{\mu m + \chi}(\mathbb{P}_2)$  and the birational map [6] to the Maruyama scheme  $\mathcal{M}_{\mathbb{P}_2^\vee}(\mu; 0, \mu)$  of semi-stable, torsionfree rank  $\mu$  sheaves with second Chern class  $\mu$  on the dual projective plane  $\mathbb{P}_2^\vee$ .

We investigated in [1], [2] the geometry of  $M_{3m+1}(\mathbb{P}_3)$  which has two smooth, rational components of dimension 12 and 13 intersecting each other transversally along an 11-dimensional smooth subvariety. It is in some sense the “smallest” example for a reducible Simpson space and plays a role similar to  $\text{Hilb}_{3m+1}(\mathbb{P}_3)$  in the case of Hilbert schemes.

Doing this, we noted as in [7] that in the planar case  $M_{3m+1}(\mathbb{P}_2)$  and  $M_{3m+2}(\mathbb{P}_2)$  are *both* isomorphic to the universal cubic  $\mathcal{C} \rightarrow \mathbb{P}_2$ . This is not an accident and turned out to be part of a more general “symmetry” result which is the subject of this short note.

FIGURE 1. Schematic Picture. Each box corresponds to an  $M_{\mu m + \chi}(\mathbb{P}_2)$ .

**Theorem 1.** Let  $P(m) = \mu m + \chi$ ,  $0 < \chi \leq \mu$ ,  $\mu$  and  $\chi$  coprime, be a linear polynomial<sup>1</sup>, and define its “dual” by  $P^\nabla(m) := \mu m + \mu - \chi$ . Denote by  $N \subset M_P(\mathbb{P}_2)$  and  $N^\nabla \subset M_{P^\nabla}(\mathbb{P}_2)$  respectively the closed subvarieties of isomorphism classes of sheaves with non-vanishing first cohomology. Then there is a natural isomorphism

$$\Phi : M_P(\mathbb{P}_2) \setminus N \xrightarrow{\cong} M_{P^\nabla}(\mathbb{P}_2) \setminus N^\nabla.$$

Thus, the moduli spaces  $M_P(\mathbb{P}_2)$  and  $M_{P^\nabla}(\mathbb{P}_2)$  are birationally equivalent. Moreover, the spaces  $M_{\mu m + 1}(\mathbb{P}_2)$  and  $M_{\mu m + \mu - 1}(\mathbb{P}_2)$  are isomorphic.

Finally, we can extend LePotier’s result cited above in a way certainly known to him:

**Theorem 2.** If  $\mu$  and  $\chi$  are coprime, the fine Simpson moduli spaces  $M_{\mu m + \chi}(\mathbb{P}_2)$  are **smooth** projective varieties of dimension  $\mu^2 + 1$ .

The author would like to thank Günther Trautmann for useful discussions.

## 2. PRELIMINARIES

We call the a projective scheme over an algebraically closed field  $k$  a *variety*. One can equip the support of a coherent sheaf  $\mathcal{F}$  on a smooth variety  $X$  in several ways with the structure

<sup>1</sup>Note that  $M_{\mu m + \tau}(\mathbb{P}_2) \cong M_{\mu m + \chi}(\mathbb{P}_2)$  if  $\tau \equiv \chi \pmod{\mu}$  since the Hilbert polynomial involved is linear.

of a (not necessarily reduced) variety. One is using the annihilator ideal sheaf  $\text{Ann}(\mathcal{F}) \subset \mathcal{O}_X$ . We write  $Z_a(\mathcal{F}) := (\text{Supp}(\mathcal{F}), \mathcal{O}_X/\text{Ann}(\mathcal{F}))$ . Another way is the following: Let

$$\bigoplus_{\mu=1}^r \mathcal{O}_X(-b_\mu) \xrightarrow{A} \bigoplus_{\nu=1}^s \mathcal{O}_X(-a_\nu) \rightarrow \mathcal{F} \rightarrow 0$$

be an arbitrary presentation of  $\mathcal{F}$  and denote by  $\text{Fitt}_i(\mathcal{F}) \subset \mathcal{O}_X$  the ideal sheaf generated by the  $(s-i) \times (s-i)$ -minors of the homogeneous matrix  $A$ . Due to Fitting's lemma, the sheaf  $\text{Fitt}_i(\mathcal{F})$  does not depend on the choice of the presentation. Furthermore, one has

$$\text{Fitt}_0(\mathcal{F}) \subset \text{Ann } \mathcal{F} \quad \text{and} \quad (\text{Ann } \mathcal{F}) \text{Fitt}_i(\mathcal{F}) \subset \text{Fitt}_{i-1}(\mathcal{F}) \quad \forall i > 0$$

Now define

$$Z_f(\mathcal{F}) := (\text{Supp}(\mathcal{F}), \mathcal{O}_X/\text{Fitt}_0(\mathcal{F})) \hookrightarrow (X, \mathcal{O}_X)$$

$Z_a(\mathcal{F})$  is obviously a subvariety of  $Z_f(\mathcal{F})$  and  $Z_a(\mathcal{F})_{\text{red}} = Z_f(\mathcal{F})_{\text{red}} = \text{Supp}(\mathcal{F})$ .

Let  $X$  be a variety and  $S$  be a Noetherian (base-)scheme of finite type over  $k$  and call the projections from  $X \times_k S$  to the first and second factor by  $q$  and  $p$  respectively. If  $\mathcal{F} \in \text{Coh}(X)$ ,  $\mathcal{G} \in \text{Coh}(S)$  and  $\mathcal{H} \in \text{Coh}(X \times S)$  are coherent sheaves, we will write  $\mathcal{F} \boxtimes \mathcal{G} := q^*\mathcal{F} \otimes p^*\mathcal{G}$ ,  $\mathcal{F}(m) \boxtimes \mathcal{O}_S := q^*\mathcal{F}(m)$ ,  $\mathcal{H}_s := \mathcal{H}|_{X \times \{s\}}$  and  $\mathcal{H}(m) := \mathcal{H} \otimes q^*\mathcal{O}_X(m)$ .

A purely 1-dimensional coherent sheaf  $\mathcal{F}$  with linear Hilbert polynomial  $P(m) = \mu m + \chi$  on a smooth variety  $X$  is called *semi-stable* resp. *stable* if for all proper coherent submodules  $0 \neq \mathcal{F}' \subset \mathcal{F}$

$$\frac{\chi(\mathcal{F}')}{\mu(\mathcal{F}')} \leq \frac{\chi}{\mu} \quad \text{resp.} \quad \frac{\chi(\mathcal{F}')}{\mu(\mathcal{F}')} < \frac{\chi}{\mu}$$

$\mu(\mathcal{F})$  is called the *multiplicity* and  $p(\mathcal{F}) := \frac{\chi}{\mu}$  the *slope* of the sheaf  $\mathcal{F}$ .

We collect now some properties of (semi-)stable sheaves supported on curves in the projective plane or projective space in the following theorem:

**Theorem 3.** *Let  $\mathcal{F}$  be a semi-stable sheaf on  $\mathbb{P}_n$ ,  $n = 2, 3$ , with linear Hilbert polynomial  $P_{\mathcal{F}}(m) = \mu m + \chi$ ,  $0 \leq \chi < \mu$  and  $C := Z_a(\mathcal{F})$  be its support.*

1.  $\mathcal{F}$  is Cohen-Macaulay, or equivalently:  $\mathcal{F}$  has no zero-dimensional torsion.
2. If  $C$  is smooth then  $\mathcal{F}$  is locally free. If  $C$  is integral  $\mathcal{F}$  is still locally free on an open dense subset  $U = C \setminus \{p_1, \dots, p_r\}$ .
3. Let  $n = 2$ . Then  $(r; c_1, c_2) = (0; \mu, \frac{\mu(\mu+3)}{2} - \chi)$ . If  $n = 3$ , we have  $(r; c_1, c_2, c_3) = (0; 0, -\mu, 2\chi - 4\mu)$  In both cases,  $r = \text{rk}_{\mathbb{P}_n}(\mathcal{F})$  denotes the rank and  $c_i = c_i(\mathcal{F})$  are the Chern classes w.r.t.  $\mathbb{P}_n$ .
4. The not necessarily reduced curve  $C \subset \mathbb{P}_n$  has no zero-dimensional components and no embedded points.
5.  $\mu = \chi(\mathcal{F}|_H)$  where  $H = Z(l) \in |\mathcal{O}_{\mathbb{P}_n}(1)|$  is  $\mathcal{F}$ -regular. Thus,

$$\mu = h^0(\mathcal{F}|_H) = \sum_{p \in C \cap H} \dim_k(\mathcal{F}_p)$$

6.  $\mu(\mathcal{O}_{C_{red}}) \leq \mu(\mathcal{O}_C) \leq \mu$  and  $\mu(\mathcal{F} \otimes \mathcal{O}_{C_{red}}) \leq \mu$
7. If  $\chi > 0$  and  $(\chi, \mu) = \mathbb{Z}$  then  $\mathcal{F}$  is stable.
8. There are the following bounds for the cohomology and the Castelnuovo-Mumford regularity of the sheaf  $\mathcal{F}$ :
  - $\chi \leq h^0 \mathcal{F} \leq \mu - 1$ .
  - $0 \leq h^1 \mathcal{F} \leq \mu - \chi - 1$ .
  - $\text{reg}(\mathcal{F}) \leq \mu - \chi$ , in particular  $H^1 \mathcal{F}(i) = 0$  for all  $i \geq \mu - \chi - 1$ .

*Proof.* Cf. [1]. The only part which is not obvious is 8.: Let  $H$  be a  $\mathcal{F}$ -regular hyperplane. Then  $0 \rightarrow \mathcal{F}(-1) \rightarrow \mathcal{F} \rightarrow \mathcal{F}|_H \rightarrow 0$  induces an exact sequence

$$(1) \quad 0 \rightarrow H^0 \mathcal{F}(n-1) \rightarrow H^0 \mathcal{F}(n) \xrightarrow{f_n} k^\mu \rightarrow H^1 \mathcal{F}(n-1) \rightarrow H^1 \mathcal{F}(n) \rightarrow 0 \quad \forall n \in \mathbb{Z}$$

This implies that  $n \mapsto h^1 \mathcal{F}(n)$  is decreasing and  $\chi \leq h^0 \mathcal{F} \leq h^0 \mathcal{F}(-1) + \mu$ . But  $\text{Hom}(\mathcal{O}_C(1), \mathcal{F})$  vanishes because of the semi-stability, and thus  $\chi \leq h^0 \mathcal{F} \leq \mu$ .

Now assume that  $f_n$  is surjective. The commutative diagram

$$\begin{array}{ccc}
 H^0 \mathcal{F}(n) \otimes H^0 \mathcal{O}(1) & \xrightarrow{f_n \otimes \text{id}} & k^\mu \otimes H^0 \mathcal{O}(1) \longrightarrow 0 \\
 \downarrow & & \downarrow \\
 H^0 \mathcal{F}(n+1) & \xrightarrow{f_{n+1}} & k^\mu \\
 & & \downarrow \\
 & & 0
 \end{array}$$

implies that  $f_{n+1}$  is also a surjection. Therefore we get

$$H^1 \mathcal{F}(n-1) \cong H^1 \mathcal{F}(n) \cong H^1 \mathcal{F}(n+1) \cong \dots \cong 0$$

by Serre's theorem B. If  $f_n$  is not surjective, then we see from the sequence (1) that  $h^1 \mathcal{F}(n-1) > h^1 \mathcal{F}(n)$ . Thus, the function  $n \mapsto h^1 \mathcal{F}(n)$  is *strictly* decreasing until it reaches 0.

Next, we show that  $h^0 \mathcal{F} \leq \mu - 1$ . Suppose  $h^0(\mathcal{F}) = \mu$ . Then the injective (!) map  $f_0$  is an isomorphism and  $\mu - \chi = h^1 \mathcal{F}(-1) = 0$ . Contradiction.

Since  $h^0 \mathcal{F} < \mu$  the homomorphism  $f_0$  cannot be surjective. The situation is then the following:

$$h^1 \mathcal{F}(n)$$

$$3\mu - \chi$$

$$2\mu - \chi$$

$$\mu - \chi$$

worst case...

$$-5 \quad -2-1 \quad \mu - \chi - 1 \quad n$$

This implies that  $\text{reg}(\mathcal{F}) \leq \mu - \chi$ . □

### 3. THE RESOLUTIONS

The key idea in the proof of theorem 1 is to find a common free resolution for all sheaves in an open subset of the moduli space  $M_{\mu, m+\chi}(\mathbb{P}_2)$  and then to dualize this resolution. An appropriate tool for this are the Beilinson complexes:

Given a coherent sheaf  $\mathcal{F}$  on  $\mathbb{P}_n$ , one has the following two complexes

$$0 \longrightarrow \mathcal{B}_{-n} \longrightarrow \cdots \longrightarrow \mathcal{B}_{-1} \longrightarrow \mathcal{B}_0 \longrightarrow \mathcal{B}_1 \longrightarrow \cdots \longrightarrow \mathcal{B}_n \longrightarrow 0$$

where

$$\mathcal{B}_p = \bigoplus_{q=0}^n H^q(\mathbb{P}_n, \mathcal{F}(p-q)) \otimes_k \Omega_{\mathbb{P}_n}^{q-p}(q-p), \quad p \in \mathbb{Z}$$

and

$$0 \longrightarrow \mathcal{C}_{-n} \longrightarrow \cdots \longrightarrow \mathcal{C}_{-1} \longrightarrow \mathcal{C}_0 \longrightarrow \mathcal{C}_1 \longrightarrow \cdots \longrightarrow \mathcal{C}_n \longrightarrow 0$$

with

$$\mathcal{C}_p = \bigoplus_{q=0}^n H^{q+p}(\mathbb{P}_n, \mathcal{F} \otimes \Omega_{\mathbb{P}_n}^q(q)) \otimes_k \mathcal{O}_{\mathbb{P}_n}(-q), \quad p \in \mathbb{Z}$$

They are exact except at  $\mathcal{B}_0$  resp.  $\mathcal{C}_0$ , where the homology is  $\mathcal{F}$ , and can be obtained from the Beilinson I/II spectral sequences. For example the second complex comes from the sequence with  $E_1$ -term

$$E_1^{rs} := H^r(\mathbb{P}_n, \mathcal{F} \otimes \Omega_{\mathbb{P}_n}^{-s}(-s)) \otimes_k \mathcal{O}_{\mathbb{P}_n}(s)$$

which converges to  $E_\infty^i = \begin{cases} \mathcal{F}, & \text{for } i=0 \\ 0, & \text{otherwise} \end{cases}$ . More detailed:  $E_\infty^{rs} = 0$  for  $r = -s$  and  $\bigoplus_{r=0}^n E_\infty^{-r,r}$  is the associated graded sheaf of a filtration of  $\mathcal{F}$ . For more details on the Beilinson sequence we refer for example to [8].

Applying this technique to semi-stable sheaves in  $\mathbb{P}_2$ , we get:

**Theorem 4.** *Let  $\mathcal{F}$  be a semi-stable sheaf on  $\mathbb{P}_2$  with linear Hilbert polynomial  $P(m) = \mu m + \chi$ ,  $0 \leq \chi < \mu$ . Furthermore, let  $a := h^0(\mathbb{P}_2, \mathcal{F} \otimes \Omega_{\mathbb{P}_2}^1(1))$ .*

(i) *There are complexes*

$$0 \rightarrow (2\mu - \chi)\mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow H^0\mathcal{F} \otimes \mathcal{O}_{\mathbb{P}_2} \oplus (\mu - \chi)\Omega_{\mathbb{P}_2}^1(1) \rightarrow H^1\mathcal{F} \otimes \mathcal{O}_{\mathbb{P}_2} \rightarrow 0$$

and

$$0 \rightarrow a\mathcal{O}_{\mathbb{P}_2}(-1) \oplus (\mu - \chi)\mathcal{O}_{\mathbb{P}_2}(-2) \rightarrow H^0\mathcal{F} \otimes \mathcal{O}_{\mathbb{P}_2} \oplus (a + \mu - 2\chi)\mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow H^1\mathcal{F} \otimes \mathcal{O}_{\mathbb{P}_2} \rightarrow 0$$

which are exact with exception of the homology sheaf in the middle which is isomorphic to  $\mathcal{F}$ . In particular, if  $H^1(\mathcal{F}) \cong 0$  we have free resolutions

$$(2) \quad 0 \rightarrow (2\mu - \chi)\mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow \chi\mathcal{O}_{\mathbb{P}_2} \oplus (\mu - \chi)\Omega_{\mathbb{P}_2}^1(1) \rightarrow \mathcal{F} \rightarrow 0$$

and

$$(3) \quad 0 \rightarrow a\mathcal{O}_{\mathbb{P}_2}(-1) \oplus (\mu - \chi)\mathcal{O}_{\mathbb{P}_2}(-2) \rightarrow \chi\mathcal{O}_{\mathbb{P}_2} \oplus (a + \mu - 2\chi)\mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow \mathcal{F} \rightarrow 0.$$

(ii) *If  $\mu(\mathcal{O}_C) < 4 - \frac{2\chi}{\mu}$  then  $h^1\mathcal{F} = 0$ .*

*Proof.* In our case, all the  $\mathcal{B}_p$  resp.  $\mathcal{C}_p$  vanish if  $p \neq -2, -1, 0, 1$ . Using the facts that  $h^0\mathcal{F}(-j) = 0$  for all  $j > 0$  because of the semi-stability and  $\Omega^2(2) = \mathcal{O}_{\mathbb{P}_2}(-1)$ , we obtain

$$\begin{aligned} \mathcal{B}_1 &= H^1\mathcal{F} \otimes \mathcal{O}_{\mathbb{P}_2} \\ \mathcal{B}_0 &= H^0\mathcal{F} \otimes \mathcal{O}_{\mathbb{P}_2} \oplus H^1\mathcal{F}(-1) \otimes \Omega^1(1) = H^0\mathcal{F} \otimes \mathcal{O}_{\mathbb{P}_2} \oplus (\mu - \chi)\Omega^1(1) \\ \mathcal{B}_{-1} &= H^0\mathcal{F}(-1) \otimes \Omega^1(1) \oplus H^1\mathcal{F}(-2) \otimes \Omega^2(2) = (2\mu - \chi)\mathcal{O}_{\mathbb{P}_2}(-1) \\ \mathcal{B}_{-2} &= H^0\mathcal{F}(-2) \otimes \Omega^2(2) = 0 \end{aligned}$$

and

$$\begin{aligned} \mathcal{C}_1 &= H^1\mathcal{F} \otimes \mathcal{O}_{\mathbb{P}_2} \\ \mathcal{C}_0 &= H^0\mathcal{F} \otimes \mathcal{O}_{\mathbb{P}_2} \oplus H^1(\mathcal{F} \otimes \Omega^1(1)) \otimes \mathcal{O}_{\mathbb{P}_2}(-1) \\ \mathcal{C}_{-1} &= H^0(\mathcal{F} \otimes \Omega^1(1)) \otimes \mathcal{O}_{\mathbb{P}_2}(-1) \oplus H^1(\mathcal{F} \otimes \Omega^2(2)) \otimes \mathcal{O}_{\mathbb{P}_2}(-2) = a\mathcal{O}_{\mathbb{P}_2}(-1) \oplus (\mu - \chi)\mathcal{O}_{\mathbb{P}_2}(-2) \\ \mathcal{C}_{-2} &= H^0(\mathcal{F} \otimes \Omega^2(2)) \otimes \mathcal{O}_{\mathbb{P}_2}(-2) = 0. \end{aligned}$$

Now consider the Euler sequence tensored with  $\mathcal{F}$

$$0 \longrightarrow \Omega^1(1) \otimes \mathcal{F} \longrightarrow 3\mathcal{F} \longrightarrow \mathcal{F}(1) \longrightarrow 0$$

in order to see that  $h^1(\mathcal{F} \otimes \Omega^1(1)) = a + \chi(\mathcal{F}(1)) - 3\chi(\mathcal{F}) = a + \mu - 2\chi$ .

To show (ii), let  $C := Z_a(\mathcal{F})$ . Then  $H^0(C, \mathcal{F} \otimes \Omega_{\mathbb{P}_2}^1(1)) \cong \text{Hom}(\mathcal{O}_C(-1) \otimes (\Omega^1)^\vee, \mathcal{F}) \cong \text{Hom}(\mathcal{O}_C(2) \otimes \Omega^1, \mathcal{F})$ .  $\mathcal{O}_C$  is stable and thus  $p$ -stable.  $\Omega^1$  is  $p$ -stable, too. The stability of

$\mathcal{O}_C(2) \otimes \Omega^1$  implies the vanishing of  $H^0(\mathcal{F} \otimes \Omega^1(1))$  if  $p(\Omega^1 \otimes \mathcal{O}_C(2)) > p(\mathcal{F})$ . But a straightforward computation using the exact sequence

$$0 \longrightarrow \Omega^1 \otimes \mathcal{O}_C(2) \longrightarrow 3\mathcal{O}_C(1) \longrightarrow \mathcal{O}_C(2) \longrightarrow 0$$

and  $p_a(C) = \frac{1}{2}(\deg(C) - 1)(\deg(C) - 2)$  gives  $p(\Omega^1 \otimes \mathcal{O}_C(2)) = 2 - \frac{\mu(\mathcal{O}_C)}{2}$  and consequently the result.  $\square$

**Remark:** The inequality  $\mu(\mathcal{O}_C) < 4 - \frac{2\chi}{\mu}$  or  $H^1(\mathcal{F}) = 0$  is for example fulfilled in the following cases:

$P(m)$	Resolution
$m$	$0 \rightarrow \mathcal{O}_{\mathbb{P}_2}(-2) \rightarrow \mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow \mathcal{F} \rightarrow 0$
$2m$	$0 \rightarrow 2\mathcal{O}_{\mathbb{P}_2}(-2) \rightarrow 2\mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow \mathcal{F} \rightarrow 0$
$2m + 1$	$0 \rightarrow \mathcal{O}_{\mathbb{P}_2}(-2) \rightarrow \mathcal{O}_{\mathbb{P}_2} \rightarrow \mathcal{F} \rightarrow 0$
$3m$	$0 \rightarrow 3\mathcal{O}_{\mathbb{P}_2}(-2) \rightarrow 3\mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow \mathcal{F} \rightarrow 0$
$3m + 1$	$0 \rightarrow 2\mathcal{O}_{\mathbb{P}_2}(-2) \rightarrow \mathcal{O}_{\mathbb{P}_2} \oplus \mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow \mathcal{F} \rightarrow 0$
$3m + 2$	$0 \rightarrow \mathcal{O}_{\mathbb{P}_2}(-2) \oplus \mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow 2\mathcal{O}_{\mathbb{P}_2} \rightarrow \mathcal{F} \rightarrow 0$

For these resolutions, one can verify that the space of matrices occurring in the resolutions modulo automorphisms is isomorphic to the corresponding moduli space  $M_P(\mathbb{P}_2)$ . This helps getting a more explicit description of the spaces:  $M_m(\mathbb{P}_2)$  is clearly isomorphic to  $\mathbb{P}_2$  since  $\mathcal{F} \cong \mathcal{O}_L(-1)$  for some line  $L$ . Leopold [5] showed that  $M_{2m}(\mathbb{P}_2) \cong M_{2m+1}(\mathbb{P}_2) \cong \mathbb{P}_5$ . In [1] or [7] one can find a proof for  $M_{3m+1}(\mathbb{P}_2) \cong M_{3m+2}(\mathbb{P}_2) \cong \mathcal{C}$ , where  $\mathcal{C} \xrightarrow{\pi} \mathbb{P}_2$  denotes the universal cubic on the projective plane. One problem occurring here is that the groups  $\text{Aut}(2\mathcal{O}_{\mathbb{P}_2}(-2)) \times \text{Aut}(\mathcal{O}_{\mathbb{P}_2} \oplus \mathcal{O}_{\mathbb{P}_2}(-1))$  and  $\text{Aut}(\mathcal{O}_{\mathbb{P}_2}(-2) \oplus \mathcal{O}_{\mathbb{P}_2}(-1)) \times \text{Aut}(2\mathcal{O}_{\mathbb{P}_2})$  divided out are not reductive.  $\square$

Now we assume for the moment  $H^1\mathcal{F} = 0$ . One would like to determine  $a = h^0(\mathcal{F} \otimes \Omega^1(1))$  in the theorem above in terms of the integers  $\mu$  and  $\chi$ . For this, we consider the following diagram where the second column is induced by the Koszul resolution

$$0 \longrightarrow \mathcal{O}_{\mathbb{P}_2}(-2) \xrightarrow{\alpha} 3\mathcal{O}_{\mathbb{P}_2}(-1) \xrightarrow{\beta} \Omega_{\mathbb{P}_2}^1(1) \longrightarrow 0$$

of the twisted cotangent bundle  $\Omega_{\mathbb{P}_2}^1(1)$ :

$$\begin{array}{ccccccc}
& & & & 0 & & \\
& & & & \uparrow & & \\
0 & \longrightarrow & (2\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-1) & \longrightarrow & \chi \mathcal{O}_{\mathbb{P}_2} \oplus (\mu - \chi) \Omega_{\mathbb{P}_2}^1(1) & \longrightarrow & \mathcal{F} \longrightarrow 0 \\
& & \parallel & & \uparrow \text{id} \times \beta & & \\
& & (2\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-1) & & \chi \mathcal{O}_{\mathbb{P}_2} \oplus 3(\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-1) & & \\
& & & & \uparrow \alpha & & \\
& & & & (\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-2) & & \\
& & & & \uparrow & & \\
& & & & 0 & & 
\end{array}$$

An application of the mapping cone lemma yields the exact sequence

$$(4) \quad 0 \rightarrow (2\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-1) \oplus (\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-2) \xrightarrow{B} \chi \mathcal{O}_{\mathbb{P}_2} \oplus 3(\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow \mathcal{F} \rightarrow 0$$

where the blockmatrix  $B$  has the shape

$$B = \left( \begin{array}{c|c} L_1 & C \\ \hline Q & L_2 \end{array} \right).$$

$Q \in \text{Mat}(\mu - \chi, \chi, k[Z_0, Z_1, Z_2]_2)$  is a matrix of quadratic forms,  $L_1$  and  $L_2$  are matrices of linear forms and  $C \in \text{Mat}(2\mu - \chi, 3\mu - 3\chi, k)$ .

This resolution is in fact not minimal. Using the semi-stability of the sheaf  $\mathcal{F}$  we can prove the following lemma:

**Lemma 1.**  $\text{rk}(C) = r' := \min\{2\mu - \chi, 3\mu - 3\chi\}$ .

*Proof.* By contradiction. Suppose  $r := \text{rk}(C) < r'$ . After deleting the appropriate rows and columns of the matrix  $B$  with the Gauß algorithm, we get

$$0 \rightarrow (2\mu - \chi - r) \mathcal{O}_{\mathbb{P}_2}(-1) \oplus (\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-2) \xrightarrow{B'} \chi \mathcal{O}_{\mathbb{P}_2} \oplus (3\mu - 3\chi - r) \mathcal{O}_{\mathbb{P}_2}(-1) \rightarrow \mathcal{F} \rightarrow 0$$

with

$$B' = \left( \begin{array}{c|c} L'_1 & 0 \\ \hline Q' & L'_2 \end{array} \right)$$

where we identify the isomorphic cokernels  $\mathcal{F}$  and  $\text{Coker}(B')$  by abuse of notation. Thus, let us investigate the diagram

$$\begin{array}{ccccccc}
& & & & & & 0 \\
& & & & & & \downarrow \\
& & & & & & \mathcal{K}_2 \\
& & & & & & \downarrow \\
0 & \longrightarrow & (2\mu - \chi - r) \mathcal{O}_{\mathbb{P}_2}(-1) & \longrightarrow & \mathcal{L}_1 & \longrightarrow & (\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-2) \longrightarrow 0 \\
& & \downarrow L'_1 & & \downarrow B' & & \downarrow L'_2 \\
0 & \longrightarrow & \chi \mathcal{O}_{\mathbb{P}_2} & \longrightarrow & \mathcal{L}_0 & \longrightarrow & (3\mu - 3\chi - r) \mathcal{O}_{\mathbb{P}_2}(-1) \longrightarrow 0 \\
& & \downarrow & & \downarrow & & \downarrow \\
& & \mathcal{C}_1 & \xrightarrow{f} & \mathcal{F} & \longrightarrow & \mathcal{C}_2 \longrightarrow 0 \\
& & \downarrow & & \downarrow & & \downarrow \\
& & 0 & & 0 & & 0
\end{array}$$

Here we write  $\mathcal{L}_1 := (2\mu - \chi - r) \mathcal{O}_{\mathbb{P}_2}(-1) \oplus (\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-2)$ ,  $\mathcal{L}_0 := \chi \mathcal{O}_{\mathbb{P}_2} \oplus (3\mu - 3\chi - r) \mathcal{O}_{\mathbb{P}_2}(-1)$  and  $\mathcal{C}_1, \mathcal{C}_2, \mathcal{K}_2$  for the cokernels respectively kernels of  $L'_1$  and  $L'_2$ . The snake lemma implies  $\text{Ker}(f) \cong \mathcal{K}_2$  and the injectivity of the map  $L'_1$ . The latter also implies forces  $2\mu - r + \chi \leq \chi$  and consequently we obtain the following bounds for  $r$ :

$$(5) \quad 2(\mu - \chi) \leq r < \min\{2\mu - \chi, 3(\mu - \chi)\}$$

If  $\chi = 0$ , we get the contradiction. Suppose now  $0 < \chi < \mu$ . After taking  $\Lambda^{2\mu - \chi - r}(\bullet)$  of the map  $L'_1$  in the first column and after dualizing and twisting, we obtain an exact sequence:

$$0 \xrightarrow{!} \binom{\chi}{2\mu - \chi - r} \mathcal{O}_{\mathbb{P}_2}(r + \chi - 2\mu) \longrightarrow \mathcal{O}_{\mathbb{P}_2} \longrightarrow \mathcal{O}_{Z_f(\mathcal{C}_1)} \longrightarrow 0$$

where  $Z_f(\mathcal{C}_1) \subset \mathbb{P}_2$  denotes the Fitting support of  $\mathcal{C}_1$ . Thus

$$P_{Z_f(\mathcal{C}_1)}(m) = \frac{1}{2} \left[ 1 - \binom{\chi}{2\mu - \chi - r} \right] m^2 + \dots$$

This forces the binomial coefficient  $\binom{\chi}{2\mu-\chi-r}$  to be 0 or 1. Using the inequalities in (5), we deduce that  $r = 2(\mu - \chi)$ . The diagram above simplifies now to

$$\begin{array}{ccccccc}
& & & & & & 0 \\
& & & & & & \downarrow \\
& & & & & & \mathcal{K}_2 \\
& & & & & & \downarrow \\
& & 0 & & 0 & & \mathcal{O}_{\mathbb{P}_2}(-2) \\
& & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & \chi \mathcal{O}_{\mathbb{P}_2}(-1) & \longrightarrow & \mathcal{L}_1 & \longrightarrow & (\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-2) \longrightarrow 0 \\
& & \downarrow L_1 & & \downarrow B' & & \downarrow L_2 \\
& & 0 & \longrightarrow & \chi \mathcal{O}_{\mathbb{P}_2} & \longrightarrow & \mathcal{L}_0 & \longrightarrow & (\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-1) \longrightarrow 0 \\
& & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & \mathcal{K}_2 & \longrightarrow & \mathcal{C}_1 & \longrightarrow & \mathcal{F} & \longrightarrow & \mathcal{C}_2 & \longrightarrow & 0 \\
& & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
& & 0 & & 0 & & 0 & & 0 & & 0
\end{array}$$

Since  $Z_a(\mathcal{C}_2) \subset Z_a(\mathcal{F})$  is zero- or one-dimensional, it follows from

$$1 = \exp.\text{codim}_{\mathbb{P}_2} Z_f(\mathcal{C}_2) \geq \text{codim}_{\mathbb{P}_2} Z_f(\mathcal{C}_2) = \text{codim}_{\mathbb{P}_2} Z_a(\mathcal{C}_2) \geq 1$$

that  $\mathcal{C}_2$  is supported on a curve and that the morphism  $L_2$  is regular. Therefore the kernel sheaf  $\mathcal{K}_2$  vanishes. An easy computation shows that the subsheaf  $\mathcal{C}_1 \subset \mathcal{F}$  has Hilbert polynomial  $P_{\mathcal{C}_1}(m) = \chi m + \chi$ . Thus we have found a 1-dimensional subsheaf of the semi-stable sheaf  $\mathcal{F}$  with

$$1 = \frac{\chi}{\chi} = \frac{\chi(\mathcal{C}_1)}{\mu(\mathcal{C}_1)} \leq \frac{\chi}{\mu} < 1.$$

Contradiction. Thus,  $r = \text{rk}(C) = \min\{2\mu - \chi, 3\mu - 3\chi\}$ .  $\square$

**Corollary 1.** *Let  $[\mathcal{F}] \in M_{\mu m + \chi}(\mathbb{P}_2)$ ,  $0 \leq \chi < \mu$  with  $H^1 \mathcal{F} = 0$ . Then  $\mathcal{F}$  has one of the following two minimal free resolutions:*

$$(6) \quad 0 \longrightarrow (\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-2) \xrightarrow{(Q|L_2)} \chi \mathcal{O}_{\mathbb{P}_2} \oplus (\mu - 2\chi) \mathcal{O}_{\mathbb{P}_2}(-1) \longrightarrow \mathcal{F} \longrightarrow 0,$$

if  $\chi \leq \frac{\mu}{2}$ .

$$(7) \quad 0 \longrightarrow (2\chi - \mu) \mathcal{O}_{\mathbb{P}_2}(-1) \oplus (\mu - \chi) \mathcal{O}_{\mathbb{P}_2}(-2) \xrightarrow{(L_1|Q)} \chi \mathcal{O}_{\mathbb{P}_2} \longrightarrow \mathcal{F} \longrightarrow 0,$$

if  $\chi \geq \frac{\mu}{2}$ .

Furthermore,

$$a = h^0(\mathbb{P}_2, \mathcal{F} \otimes \Omega_{\mathbb{P}_2}^1(1)) = \begin{cases} 0 & , \quad \chi \leq \frac{\mu}{2} \\ 2\chi - \mu & , \quad \chi > \frac{\mu}{2} \end{cases}$$

*Proof.* Consider the blockmatrix  $B = \left( \begin{array}{c|c} L_1 & C \\ \hline Q & L_2 \end{array} \right)$  in the exact sequence (4). Lemma 1 says that  $\text{rk}(C) = \min\{2\mu - \chi, 3\mu - 3\chi\}$ . Therefore, the resolution (6) can be obtained by deleting the last  $3\mu - 3\chi$  columns of  $B$  if  $\text{rk}(C) = 3\mu - 3\chi$ . Similarly, one gets (7) by killing the first  $2\mu - \chi$  rows of  $B$  with Gauß' algorithm in case of  $\text{rk}(C) = 2\mu - \chi$ . Comparing (6) and (7) with the resolution (3) in theorem 4.(i), we also obtain the value for  $a = h^0(\mathcal{F} \otimes \Omega_{\mathbb{P}_2}^1(1))$ .  $\square$

**Remark:** In the case  $\chi = \mu - 1$  one has  $H^1\mathcal{F} = 0$  for all  $[\mathcal{F}] \in M_{\mu m + \mu - 1}(\mathbb{P}_2)$  since  $\text{reg}(\mathcal{F}) \leq 1$  according to theorem 3.(8). The resolution is therefore in this case:

$$0 \longrightarrow \mathcal{O}_{\mathbb{P}_2}(-2) \oplus (\mu - 2) \mathcal{O}_{\mathbb{P}_2}(-1) \xrightarrow[A]{} (\mu - 1) \mathcal{O}_{\mathbb{P}_2} \longrightarrow \mathcal{F} \longrightarrow 0$$

M. Maican used this free resolution in order to prove that the moduli spaces  $M_{\mu m + \mu - 1}(\mathbb{P}_2)$  can be described as geometric quotients of maps  $A$  by the non-reductive group

$$G := \text{Aut}((\mu - 2) \mathcal{O}_{\mathbb{P}_2}(-2) \oplus \mathcal{O}_{\mathbb{P}_2}(-1)) \times \text{Aut}((\mu - 1) \mathcal{O}_{\mathbb{P}_2})$$

using a suitable polarization.  $\square$

We also need a “relative version” of corollary 1 for families. As in the absolute case, there exists for any  $\mathcal{F} \in \text{Coh}(\mathbb{P}_n \times S)$  a Beilinson-type spectral sequence with  $E_1$ -term

$$E_1^{rs} = \mathcal{O}_{\mathbb{P}_2}(r) \boxtimes R^s p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_n \times S/S}^{-s}(-s))$$

which converges to  $E_\infty^i = \begin{cases} \mathcal{F}, & \text{for } i=0 \\ 0, & \text{otherwise} \end{cases}$ , i.e.  $E_\infty^{rs} = 0$  for  $r + s \neq 0$  and  $\bigoplus_{r=0}^n E_\infty^{-r,r}$  is the associated graded sheaf of a filtration of  $\mathcal{F}$  (cf. [8], p.306). Again, the spectral sequence gives rise to a complex

$$0 \longrightarrow \mathcal{C}_{-n} \longrightarrow \cdots \longrightarrow \mathcal{C}_{-1} \longrightarrow \mathcal{C}_0 \longrightarrow \mathcal{C}_1 \longrightarrow \cdots \longrightarrow \mathcal{C}_n \longrightarrow 0$$

with

$$\mathcal{C}_p = \bigoplus_{q=0}^n \mathcal{O}_{\mathbb{P}_n}(-q) \boxtimes R^{q+p} p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_n \times S/S}^q(q))$$

which is exact everywhere with exception of  $\mathcal{C}_0$ , where the homology is  $\mathcal{F}$ .

Now let  $\mathcal{F} \in \text{Coh}(\mathbb{P}_2 \times S)$  be a family of semi-stable sheaves  $\mathcal{F}_s$  with Hilbert polynomial  $P_{\mathcal{F}_s}(m) = \mu m + \chi$  and  $H^1(\mathbb{P}_2, \mathcal{F}_s) = 0$  for all  $s \in S$ . Using the base change theorem and exactly the same arguments as in the proof of theorem 4.(i), we obtain a non-minimal (!) exact sequence

$$\begin{array}{ccccccc} 0 & \longrightarrow & [\mathcal{O}_{\mathbb{P}_2}(-1) \boxtimes p_*(\mathcal{F} \otimes \Omega^1(1))] \oplus [\mathcal{O}_{\mathbb{P}_2}(-2) \boxtimes R^1 p_* \mathcal{F}(-1)] & \xrightarrow{B_s} & & & \\ & \xrightarrow{B_s} & [\mathcal{O}_{\mathbb{P}_2} \boxtimes p_* \mathcal{F}] \oplus [\mathcal{O}_{\mathbb{P}_2}(-1) \boxtimes R^1 p_*(\mathcal{F} \otimes \Omega^1(1))] & & \longrightarrow & \mathcal{F} & \longrightarrow 0 \end{array}$$

*Proof.* To give a flavour of how to proceed, we show for example why  $p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^2(2)) = 0$  (and consequently  $\mathcal{C}_{-2} = 0$ ):

Since all the sheaves  $\mathcal{F}_s$  are supported on curves one has  $H^2(\mathbb{P}_2, \mathcal{F}_s(-1)) = 0$ . The base change theorem implies that  $R^1 p_* \mathcal{F}(-1)(s) \xrightarrow{\cong} H^1(\mathbb{P}_2, \mathcal{F}_s(-1))$  for all  $s \in S$ . Therefore  $R^1 p_* \mathcal{F}(-1)$  is locally free. Another application of the base change theorem yields  $p_* \mathcal{F}(-1)(s) \cong H^0(\mathbb{P}_2, \mathcal{F}_s(-1))$ . But then

$$0 = \text{Hom}(\mathcal{O}_{\mathbb{P}_2}, \mathcal{F}_s(-1)) \cong H^0(\mathbb{P}_2, \mathcal{F}_s(-1)) \quad \forall s \in S,$$

due to the semi-stability of  $\mathcal{F}_s$ . Thus,  $p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^2(2)) \cong p_* \mathcal{F}(-1) = 0$ .  $\square$

By looking at the rank of the constant block in the family of matrices  $(B_s)_{s \in S}$  as we did it for the absolute case in lemma 1, we can simplify the resolution and obtain the analogon to corollary 1:

**Theorem 5.** *Let  $[\mathcal{F}] \in \mathcal{M}_{\mu m + \chi}(\mathbb{P}_2)(S)$ ,  $0 \leq \chi < \mu$  with  $H^1(\mathbb{P}_2, \mathcal{F}_s) = 0$  for all  $s \in S$ . Then  $\mathcal{F}$  has one of the following two minimal free resolutions:*

(8)

$$0 \rightarrow \mathcal{O}_{\mathbb{P}_2}(-2) \boxtimes R^1 p_* \mathcal{F}(-1) \rightarrow \mathcal{O}_{\mathbb{P}_2} \boxtimes p_* \mathcal{F} \oplus \mathcal{O}_{\mathbb{P}_2}(-1) \boxtimes R^1 p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1)) \rightarrow \mathcal{F} \rightarrow 0,$$

if  $\chi \leq \frac{\mu}{2}$ .

(9)

$$0 \rightarrow \mathcal{O}_{\mathbb{P}_2}(-1) \boxtimes p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1)) \oplus \mathcal{O}_{\mathbb{P}_2}(-2) \boxtimes R^1 p_* \mathcal{F}(-1) \rightarrow \mathcal{O}_{\mathbb{P}_2} \boxtimes p_* \mathcal{F} \rightarrow \mathcal{F} \rightarrow 0,$$

if  $\chi \geq \frac{\mu}{2}$ .

Moreover,

- $p_* \mathcal{F}$  and  $R^1 p_* \mathcal{F}(-1)$  are locally free of rank  $\chi$  and  $\mu - \chi$  respectively.
- $p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1))$  and  $R^1 p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1))$  are locally free.
  - If  $\chi \leq \frac{\mu}{2}$  then  $p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1)) = 0$  and  $\text{rk} \left[ R^1 p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1)) \right] = \mu - 2\chi$ .
  - If  $\chi > \frac{\mu}{2}$  then  $\text{rk} \left[ p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1)) \right] = 2\chi - \mu$  and  $R^1 p_*(\mathcal{F} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1)) = 0$ .

*Proof.* Left to the reader.  $\square$

#### 4. DUAL SHEAVES

We define for a (semi-)stable sheaf  $\mathcal{F}$  on  $\mathbb{P}_2$  with linear Hilbert polynomial  $P(m) = \mu m + \chi$  its dual sheaf by

$$\mathcal{F}^\vee := \mathcal{E}xt_{\mathcal{O}_{\mathbb{P}_2}}^1(\mathcal{F}, \omega_{\mathbb{P}_2})(1)$$

$\text{Hom}_{\mathcal{O}_{\mathbb{P}_2}}(\mathcal{F}, \omega_{\mathbb{P}_2}) = 0$  since  $\mathcal{F}$  is pure with one-dimensional support. Thus, dualizing the minimal free resolution (6) or (7) of  $\mathcal{F}$  from the corollary above and twisting by  $\bullet \otimes \mathcal{O}_{\mathbb{P}_2}(-2)$

implies that  $\mathcal{F}^\nabla$  is (semi-)stable with Hilbert-polynomial  $P^\nabla(m) := \mu m + (\mu - \chi)$ . For example, if  $\chi \leq \frac{\mu}{2}$  we obtain

$$0 \longrightarrow \chi \mathcal{O}_{\mathbb{P}_2}(-2) \oplus (\mu - 2\chi) \mathcal{O}_{\mathbb{P}_2}(-1) \longrightarrow (\mu - \chi) \mathcal{O}_{\mathbb{P}_2} \longrightarrow \mathcal{F}^\nabla \xrightarrow{!} 0$$

by this procedure.

Moreover, one can verify immediately that:

- $\mathcal{F}^{\nabla\nabla} \cong \mathcal{F}$
- $H^1 \mathcal{F} = 0 \iff H^1 \mathcal{F}^\nabla = 0$

Thus, we get our main result:

**Theorem 6.** *Let  $P(m) = \mu m + \chi$  be a linear polynomial with  $0 \leq \chi < \mu$  and  $(\mu, \chi) = \mathbb{Z}$ . Denote by  $N \subset M_P(\mathbb{P}_2)$  respectively  $N^\nabla \subset M_{P^\nabla}(\mathbb{P}_2)$  the closed subvarieties of isomorphism classes of sheaves with non-vanishing first cohomology. Then there is a natural isomorphism*

$$\phi : M_P(\mathbb{P}_2) \setminus N \xrightarrow{\sim} M_{P^\nabla}(\mathbb{P}_2) \setminus N^\nabla, \quad [\mathcal{F}] \mapsto [\mathcal{F}^\nabla]$$

Thus, the moduli spaces  $M_P(\mathbb{P}_2)$  and  $M_{P^\nabla}(\mathbb{P}_2)$  are birationally equivalent.

*Proof.* Clearly, the remarks above show that  $\phi$  is set-theoretically a bijection. In order to show that  $\phi$  is actually a morphism, note that  $M := M_P(\mathbb{P}_2)$  is a fine moduli space with universal family  $\mathcal{U} \in \mathcal{M}_P(\mathbb{P}_2)(M)$  since  $\mu$  and  $\chi$  are coprime. Without loss of generality, we can assume that  $\chi \leq \frac{\mu}{2}$ . Now consider the minimal free resolution (8) of  $\mathcal{C} := \mathcal{U}|_{\mathbb{P}_2 \times M \setminus N}$  from theorem 5:

$$0 \longrightarrow \mathcal{O}_{\mathbb{P}_2}(-2) \boxtimes R^1 p_* \mathcal{C}(-1) \longrightarrow \mathcal{O}_{\mathbb{P}_2} \boxtimes p_* \mathcal{C} \oplus \mathcal{O}_{\mathbb{P}_2}(-1) \boxtimes R^1 p_*(\mathcal{C} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1)) \longrightarrow \mathcal{C} \longrightarrow 0.$$

An application of  $\mathcal{H}om_{\mathcal{O}_{\mathbb{P}_2 \times M \setminus N}}(\bullet, \mathcal{O}_{\mathbb{P}_2}(-2) \boxtimes \mathcal{O}_{M \setminus N})$  yields:

$$0 \rightarrow \mathcal{O}_{\mathbb{P}_2}(-2) \boxtimes [p_* \mathcal{C}]^* \oplus \mathcal{O}_{\mathbb{P}_2}(-1) \boxtimes [R^1 p_*(\mathcal{C} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1))]^* \longrightarrow \mathcal{O}_{\mathbb{P}_2} \boxtimes [R^1 p_* \mathcal{C}(-1)]^* \longrightarrow \mathcal{G} \rightarrow 0,$$

where  $\mathcal{G} = \mathcal{E}xt_{\mathcal{O}_{\mathbb{P}_2 \times M \setminus N}}^1(\mathcal{C}, \mathcal{O}_{\mathbb{P}_2}(-2) \boxtimes \mathcal{O}_{M \setminus N})$ .

According to theorem 5, the bundles  $[p_* \mathcal{C}]^*$ ,  $[R^1 p_*(\mathcal{C} \otimes \Omega_{\mathbb{P}_2 \times S/S}^1(1))]^*$  and  $[R^1 p_* \mathcal{C}(-1)]^*$  have rank  $\chi$ ,  $\mu - 2\chi$  and  $\mu - \chi$  respectively. Thus, the restriction of the resolution to a fiber  $\mathcal{G}_{[\mathcal{F}]}$  is

$$0 \longrightarrow \chi \mathcal{O}_{\mathbb{P}_2}(-2) \oplus (\mu - 2\chi) \mathcal{O}_{\mathbb{P}_2}(-1) \longrightarrow (\mu - \chi) \mathcal{O}_{\mathbb{P}_2} \longrightarrow \mathcal{G}_{[\mathcal{F}]} \longrightarrow 0$$

which is exactly the resolution of  $\mathcal{F}^\nabla$  obtained above. Therefore  $\mathcal{G}_{[\mathcal{F}]} \cong \mathcal{F}^\nabla$ . Obviously, the sheaves  $\mathcal{G}_{[\mathcal{F}]}$  are stable with Hilbert polynomial  $P^\nabla(m) = \mu m + (\mu - \chi)$  and  $H^1 \mathcal{G}_{[\mathcal{F}]} = 0$  for all  $[\mathcal{F}] \in M \setminus N$ . In other words,  $\mathcal{G} \in \mathcal{M}_{P^\nabla}(\mathbb{P}_2)(M \setminus N)$ . Per construction, the **morphism**

$$\Phi_{\mathcal{G}} : M \setminus N \longrightarrow M_{P^\nabla}(\mathbb{P}_2)$$

induced by the family  $\mathcal{G}$  maps to  $M_{P^\nabla}(\mathbb{P}_2) \setminus N^\nabla$  and is indeed equal to the set-theoretical map  $\phi$ . Similarly, one proves that  $\phi^{-1}$  is a morphism.  $\square$

## 5. SMOOTHNESS

In this section we want to reprove LePotier's result that  $M_{\mu m + \chi}(\mathbb{P}_2)$  for coprime coefficients and show that the irreducible moduli space [7] is then indeed smooth.

**Theorem 7.** *Let  $P(m) := \mu m + \chi$  with  $(\mu, \chi) = (1)$ . Then*

1.  $M := M_P(\mathbb{P}_2)$  is a smooth projective variety of dimension  $\mu^2 + 1$ .
2. The moduli space  $M$  is fine with universal family  $\mathcal{U} \in \mathcal{M}_P(\mathbb{P}_2)(M)$ .

*Proof.* Without loss of generality we can assume that  $0 \leq \chi < \mu$ . By theorem 3.(7), we have that all semi-stable sheaves  $\mathcal{F}$  with polynomial  $P$  are stable.

1. Serre duality gives  $\text{Ext}^2(\mathcal{F}, \mathcal{F}) = \text{Hom}(\mathcal{F}, \mathcal{F} \otimes \omega_{\mathbb{P}_2})^\vee = \text{Hom}(\mathcal{F}, \mathcal{F}(-3))^\vee = 0$  for every  $[\mathcal{F}] \in M$ . The last equality is due to the stability of  $\mathcal{F}$ . Id est, there are no obstructions and  $M$  is smooth in neighbourhood of  $[\mathcal{F}]$ . Consequently,  $M$  is a smooth projective variety. We are left to compute  $\dim M$ . Every sheaf in the open, dense subset  $M \setminus N = \{[\mathcal{F}] \in M_P(\mathbb{P}_2) : H^1 \mathcal{F} = 0\}$  has a resolution (2). If we apply  $\text{Hom}(\cdot, \mathcal{F})$  to that sequence, we end up with

$$0 \longrightarrow \text{End}(\mathcal{F}) \longrightarrow \chi H^0 \mathcal{F} \oplus (\mu - \chi) \text{Hom}(\Omega_{\mathbb{P}_2}^1(1), \mathcal{F}) \longrightarrow (2\mu - \chi) H^0 \mathcal{F}(1) \longrightarrow \text{Ext}^1(\mathcal{F}, \mathcal{F}) \longrightarrow \dots \longrightarrow \chi H^1 \mathcal{F} \oplus (\mu - \chi) \text{Ext}^1(\Omega_{\mathbb{P}_2}^1(1), \mathcal{F}) \longrightarrow (2\mu - \chi) H^1 \mathcal{F}(1) \longrightarrow \text{Ext}^2(\mathcal{F}, \mathcal{F}) \longrightarrow 0$$

The stable sheaf  $\mathcal{F}$  is simple and therefore  $\text{End}(\mathcal{F}) \cong k$ . We also have  $\text{Hom}(\Omega_{\mathbb{P}_2}^1(1), \mathcal{F}) \cong H^0(\mathcal{F}(-1) \otimes (\Omega_{\mathbb{P}_2}^1)^\vee) \cong H^0(\mathcal{F}(2) \otimes \Omega_{\mathbb{P}_2}^1)$  and  $\text{Ext}^1(\Omega_{\mathbb{P}_2}^1(1), \mathcal{F}) \cong H^1(\mathcal{F}(2) \otimes \Omega_{\mathbb{P}_2}^1)$ . Using the Euler sequence

$$0 \rightarrow \mathcal{F}(2) \otimes \Omega_{\mathbb{P}_2}^1 \rightarrow 3\mathcal{F}(1) \rightarrow \mathcal{F}(2) \rightarrow 0,$$

we get  $\chi(\mathcal{F}(2) \otimes \Omega_{\mathbb{P}_2}^1) = 3\chi(\mathcal{F}(1)) - \chi(\mathcal{F}(2)) = \mu + 2\chi$ . But then:

$$\begin{aligned} \text{ext}^1(\mathcal{F}, \mathcal{F}) &= 1 - \chi h^0 \mathcal{F} - (\mu - \chi) h^0(\mathcal{F}(2) \otimes \Omega^1) + (2\mu - \chi) h^0 \mathcal{F}(1) + \\ &\quad \chi h^1 \mathcal{F} + (\mu - \chi) h^1(\mathcal{F}(2) \otimes \Omega^1) - (2\mu - \chi) h^1 \mathcal{F}(1) \\ &= 1 - \chi^2 - (\mu - \chi)\chi(\mathcal{F}(2) \otimes \Omega^1) + (2\mu - \chi)\chi(\mathcal{F}(1)) \\ &= 1 - \chi^2 - (\mu - \chi)(\mu + 2\chi) + (2\mu - \chi)(\mu + \chi) \\ &= \mu^2 + 1. \end{aligned}$$

Thus  $\dim M = \mu^2 + 1$  because  $\dim_k T_{[\mathcal{F}]} M = \mu^2 + 1$  for all  $[\mathcal{F}] \in M \setminus N$ .

2. The existence and construction of the universal family in this case is standard and can be found for example in [3].

□

**Remark 1:** Let again  $\chi = \mu - 1$ ,  $\mu > 1$ . In this case we have  $N = \emptyset$ . Thus, there is an isomorphism between the smooth,  $(\mu^2 + 1)$ -dimensional, fine moduli spaces  $M_{\mu m + 1}(\mathbb{P}_2)$  and  $M_{\mu m + \mu - 1}(\mathbb{P}_2)$ .

**Remark 2:** [7]. If  $\mu$  and  $\chi$  are *not* coprime and  $\mu \geq 2$  then the complement of the open subset of stable sheaves in  $M_{\mu m + \chi}(\mathbb{P}_2)$  has codimension at least  $2\mu - 3$ , and no matter what open set  $U$  in  $M_{\mu m + \chi}(\mathbb{P}_2)$  one chooses, there does not exist a universal sheaf over  $\mathbb{P}_2 \times U$ .
