 Canonical Conditional Rewrite Systems
 Containing Extra Variables

 Abstract

 We study deterministic conditional rewrite systems, i.e. conditional rewrite systems
 where the extra variables are not totally free but 'input bounded'. If such a system
 $R$ is quasi-reductive then $\rightarrow_R$ is decidable and terminating. We develop a critical pair
 criterion to prove confluence if $R$ is quasi-reductive and strongly deterministic. In this
 case we prove that $R$ is logical, i.e. $\iff R = \iff_R$ holds. We apply our results to prove
 Horn clause programs to be uniquely terminating.

 *This research was supported by the Deutsche Forschungsgemeinschaft, SFB 314, Project D4
1 Introduction

Conditional rewrite systems are widely used as a high-level language to write functional programs. This may cause non-deterministic computations. So one wants to prove that such a system \( R \) is canonical, i.e. terminating and confluent. This guarantees that for any input all possible computations stop and give the same result. There are well-known methods to prove termination and confluence if no extra variables are allowed. See [DO90] for a survey.

Functional programming naturally demands for the \textit{where}-construct and this construct can be incorporated into the rewrite system approach only by allowing extra variables. But extra variables should be allowed only in a very restricted form since it is not clear how to instantiate them when only the variables in the left-hand side of a rule are instantiated for rewriting. So in this paper we restrict to deterministic rewrite rules (see [Ga91] and [BG89] for this notion): We require that the extra variables are 'input bounded'. In [Ga91] it is proved that \( \rightarrow_R \) is decidable and terminating if \( R \) is quasi-reductive. We prove that \( \rightarrow_R \) is confluent if \( R \) is in addition strongly deterministic and all proper critical pairs are joinable. Note that no paramodulation pairs (overlapping into the conditions) and no resolution pairs (factoring of a condition) need to be computed. These pairs may be harmful for arbitrary conditional rewrite systems with extra variables [Ga91], [De91]. As far as critical pairs are concerned, we neither need to consider variable overappings nor overappings of a rule with itself on top level. (Both are needed if \( R \) is not strongly deterministic.)

For many strongly deterministic rewrite systems \( R \) encountered in practice it can be proved that all proper critical pairs are either unfeasible or context-joinable. Then \( R \) will be confluent, provided it is quasi-reductive.

If \( R \) is a standard conditional rewrite system in the sense of [DO90] and confluent then \( R \) is logical, i.e. \( \leftarrow \rightarrow_R \) equals the \( \text{R-equality} \rightarrow_R \). This is not true for a strongly deterministic \( R \), one needs in addition the termination of \( R \) or a restriction on the right-hand sides of the condition in the rules that is more restrictive than strong determinism.

The class of strongly deterministic rewrite systems seems to be interesting for two reasons. First, interesting problems can be specified rather naturally. And second, well-moded Horn clause programs can be translated into this class of rewrite systems (see [GW92]). We show how to prove that a well-moded program is uniquely terminating: Any derivation starting with a well-moded query stops and all refutations give the same answer substitution.

The paper is organized as follows: In section 2 we give the basic notations. We discuss the condition 'quasi-reductive' in section 3 and confluence in section 4. We show that \( \rightarrow_R \) is logical under the conditions mentioned above in section 5 and we prove logic programs to be uniquely terminating in section 6.

Our interest in studying deterministic rewrite systems stems from problems arising in the field of program synthesis [LS92]. Here conditional rewrite systems with extra variables naturally appear.

The results of section 3 are basically contained in [BG89]. We present them here to make the paper self-contained. Beyond that we present an interesting method to prove quasi-reductivity. This is done by incorporating given inequalities in the definition of the recursive path ordering in order to compare terms with extra variables.

Some of the results presented in section 4 are also implicitely contained in [BG89]. The main differences are: (1) We do not want to start a completion algorithm but we want a simple
test on confluence for a given deterministic quasi-reductive rewrite system. We believe that many 'natural specifications' occurring in practice are really confluent (or at least ground confluent). (2) We do not want to use the concept of a non-operational equation. (3) To test confluence we prove that critical pairs resulting from overlapping a rule by itself on top-level need not be considered.

In [BG89] a result is reported that every absolutely deterministic, quasi-reductive and confluent $R$ is logical. Here we show that one either needs additional restrictions on the right-hand sides of the conditions in a rule and no termination or termination and only strong determinism for a confluent $R$ to be logical.

To study unique termination of well-moded logic programs we follow [HA85] and [GW92]. In [GW92] only termination of derivations in well-moded logic programs is studied. We use the translation of well-moded logic programs into deterministic rewrite systems from that paper to extend results from [HA85].

2 Basic notations

We assume the reader to be familiar with basic rewriting techniques and notations. For survey papers we refer to [AM90] and [DJ90] and especially for conditional rewriting to [DO90].

A signature is a triple $\sigma = (S, F, \tau)$. Here $S$ is a set of sorts, $F$ a set of operators and $\tau$ a function $\tau: F \rightarrow S^+$ denoting the arity of the operators. $T(\mathcal{F}, V)$ is the set of terms over $\mathcal{F}$ and a set $V$ of variables. A term is ground if it contains no variable. For a term $t$ we denote by $O(t)$ the set of positions $p$ in $t$ such that $t/p$ is not a variable. We denote by $t[s]_p$ the term that results from $t$ by replacing $t/p$ by $s$. We write $\equiv$ for the syntactic identity of terms. $\text{Var}(o)$ is the set of variable occurring in an object (term, equation, ...) $o$.

A partial ordering $\succ$ on $T(\mathcal{F}, V)$ is well-founded if there is no infinite sequence $t_0 \succ t_1 \succ t_2 \succ \cdots$. It is compatible with substitutions (the term structure), if $s \succ s'$ implies $\sigma(s) \succ \sigma(s')$ for any substitution $\sigma$ (respectively, $t[s]_p \succ t[s']_p$ for any term $t$ and position $p$ in $t$). A reduction ordering is a partial ordering that is well-founded, compatible with substitutions and compatible with the term structure. We denote by $\prec$ the proper subterm relation and by $\succ_{st} = (\succ \cup \prec) +$ the smallest ordering that contains $\succ$ and $\prec$. It is well-founded if $\succ$ is well-founded and compatible with the term structure. There are well-known methods to construct reduction orderings, we mention the recursive path ordering RPO and the lexicographic path ordering LPO. For these orderings we have $\succ = \succ_{st}$. For a survey paper on orderings see [De87].

We study conditional rewrite systems with extra variables. In this case it is convenient to consider oriented conditions. An unconditional oriented equation is a pair of terms, written $u \rightarrow v$. An oriented condition $C$ is a finite sequence of unconditional oriented equations $C \equiv u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n$. It is called operational for a set $V_0$ of variables if

$$\text{Var}(u_i) \subseteq V_0 \cup \text{Var}(u_1 \rightarrow v_1) \cup \ldots \cup \text{Var}(u_{i-1} \rightarrow v_{i-1})$$

for $i = 1, \ldots, n$. (This implies $\text{Var}(u_1) \subseteq V_0$). Let $R$ be a rewrite system such that $\rightarrow_R$ is already defined. A substitution $\sigma$ is a solution of $C \equiv u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n$ wrt. $R$ and $V_0$ if

$$\sigma(u_i) \rightarrow_R \sigma(v_i) \quad \text{for all } 1 \leq i \leq n$$

$$\text{Var}(\sigma(x)) \subseteq \text{Var}(\sigma(V_0)) \quad \text{for all } x \in \text{Var}(C)$$
\( \sigma \) is irreducible if \( \sigma(x) \) is irreducible for all \( x \in V \). \( \sigma \) extends \( \tau \) with \( \text{Dom}(\tau) = V_0 \) if \( \sigma(x) \equiv \tau(x) \) for all \( x \in V_0 \). If \( C \) is empty then every \( \sigma \) is a solution of \( C \) wrt. \( R \) and \( V_0 \).

Note that the problem to compute all solutions of \( C \) that extend \( \tau \) reduces to rewriting and matching. So, if \( \rightarrow_R \) is computable and terminating then the set of solutions of \( C \) wrt. to \( R \) and \( V_0 \) that extend \( \tau \) is finite and computable.

**Example 2.1**

\[
R : \quad 0 + y \rightarrow y \quad 0 \ast y \rightarrow 0 \\
\quad s(x) + z \rightarrow x + s(y) \quad s(x) \ast y \rightarrow y + (x \ast y)
\]

\( C \equiv x + y \rightarrow x' + y' \), \( x' \ast y' \rightarrow z \)

Let \( V_0 = \{x, y\} \) and \( \tau = \{x \leftarrow s^n(0), y \leftarrow s^m(0)\} \). Then for all solutions \( \sigma \) extending \( \tau \) we have \( \sigma(z) \in \{s^k(0) \mid k = i \cdot j, i + j = n + m\} \).

**Definition 2.1** A deterministic rule is a formula \( C \implies l \rightarrow r \) such that \( C \equiv u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \) is operational for \( \text{Var}(l) \) and \( \text{Var}(r) \subseteq \text{Var}(l) \cup \text{Var}(C) \) and \( l \) is not a variable. The set of extra variables of this rule is \( \text{EV} \text{ar}(C) \implies l \rightarrow r = \text{Var}(C) - \text{Var}(l) \).

A deterministic term rewrite system (DTRS) is a finite set \( R \) of deterministic rules.

We simply write \( l \rightarrow r \) instead of \( C \implies l \rightarrow r \) if \( C \) is empty. We next define the rewrite relation \( \rightarrow_R \) for a DTRS \( R \).

**Definition 2.2** Let \( R \) be a DTRS. The rewrite relation \( \rightarrow_R \) is the smallest relation satisfying \( t[l](\sigma) \rightarrow t[r](\sigma) \), whenever \( C \implies l \rightarrow r \) is a rule in \( R \) and \( \sigma \) is a solution of \( C \) wrt. \( R \) and \( \text{Var}(l) \).

Note that \( s \rightarrow_R t \) implies \( \text{Var}(t) \subseteq \text{Var}(s) \). Note also that \( \rightarrow_R \) is defined recursively. To make this recursion explicit we define the approximation of \( R \) as an infinite sequence \( (R_i)_{i \geq 0} \) of unconditional rewrite systems

\[
R_0 = \{ l \rightarrow r \mid l \rightarrow r \text{ in } R \} \\
R_{i+1} = R_i \cup \{ \sigma(l) \rightarrow \sigma(r) \mid C \implies l \rightarrow r \text{ in } R, \sigma \text{ a solution of } C \text{ wrt. } R_i \text{ and } \text{Var}(l) \}
\]

We have \( s \rightarrow_R t \) iff \( s \rightarrow_{R_i} t \) for some \( i \geq 0 \).

We have defined a DTRS with oriented conditions. Such a system is called a normal conditional rewrite system in [DO90]. There are some other ways to evaluate the conditions. If a condition \( u = v \) is to be evaluated by a joinability test then we write \( u \downarrow v \). A system with a joinability test for the conditions is called a standard conditional rewrite system in [DO90]. For functional programming it is reasonable to allow both sorts of conditions, one for testing and the other one for computing. So a rule would be of the form

\[
u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n, s_1 \downarrow t_1, \ldots, s_m \downarrow t_m \implies l \rightarrow r
\]

The conditions \( s_i \downarrow t_i \) can easily be transformed into oriented conditions \( s_i \leftarrow x_i, t_i \rightarrow x_i \) using new extra variables \( x_i \). For this reason we only allow oriented conditions. In the next section we will consider quasi-reductive rules only in order to have \( \rightarrow_R \) decidable and terminating. For standard conditional rewriting the conditions 'reductive' and 'decreasing' are needed for the same purpose. It will be easy to see that, given a decreasing standard
rule $s_1 \mid t_1, \ldots, s_m \mid t_m \Rightarrow l \rightarrow r$ with no extra variables, then the transformed rule $s_1 \rightarrow x_1, t_1 \rightarrow x_1, \ldots, s_m \rightarrow x_m, t_m \rightarrow x_m \Rightarrow l \rightarrow r$ is deterministic and quasi-reductive. So our approach is a generalization of standard conditional rewriting.

For standard conditional rewriting we have: If $s \rightarrow_R t$ then (i) $\sigma(s) \rightarrow_R \sigma(t)$ for any substitution $\sigma$ and (ii) $t_0[s]_p \rightarrow t_0[t]_p$ for any position $p$ in $t_0$. This holds also if $R$ is a DTRS. The claim (ii) is trivial and (i) is proved by induction on $i$ for the approximation $(R_i)_{i \geq 0}$ of $R$: If $s \rightarrow_R t$ then $\sigma(s) \rightarrow_{R_i} \sigma(t)$. We need this fact in the proof of Theorem 4.1.

3 Quasi-reductive DTRSs

Now we impose a condition on DTRSs $R$ so that $\rightarrow_R$ is computable and terminating [GW92].

**Definition 3.1**

Let $\succ$ be a reduction ordering on $T(F, V)$. A DTRS $R$ is quasi-reductive wrt. $\succ$ if for every substitution $\sigma$ and every rule $u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \Rightarrow l \rightarrow r$ in $R$

(i) $\sigma(u_j) \trianglerighteq \sigma(v_j)$ for $1 \leq j \leq i$ implies $\sigma(l) \trianglerighteq \sigma(u_{i+1})$

(ii) $\sigma(u_j) \trianglerighteq \sigma(v_j)$ for $1 \leq j \leq n$ implies $\sigma(l) \trianglerighteq \sigma(r)$

A DTRS $R$ is called quasi-reductive if there is a reduction ordering $\succ$ such that $R$ is quasi-reductive wrt. $\succ$.

Now we prove that a quasi-reductive DTRS can be used for effective computations. We make this precise in Theorem 3.1 (see [GW92]). Let $\Delta^*_R(t) = \{ s \mid t \rightarrow^*_R s \}$ denote the set of $R$-successors of $t$.

**Theorem 3.1** Let $R$ be a DTRS that is quasi-reductive wrt. $\succ$. Then for every term $t$ the set $\Delta^*_R(t)$ is finite and effectively computable. We have $\rightarrow_R \subseteq \succ$, so $R$ is terminating.

**Proof:** Let $R$ be quasi-reductive wrt. $\succ$. We prove the statement of the Theorem by induction on $\succ_{st}$. We have $l \rightarrow_R s$ if there is a position $p$ in $t$, a rule $C \Rightarrow l \rightarrow r$ in $R$ and a substitution $\sigma$ such that $\sigma(l) \equiv t/p$ and $\sigma$ is a solution of $C$ wrt. $R$ and $Var(l)$. Since $R$ is finite it is enough to prove that for each rule $C \Rightarrow l \rightarrow r$ there are only finitely many such solutions and one can compute them all.

Let $C \equiv u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n$ and $r$ be given such that $r(l) \equiv t/p$ and $Dom(\tau) = Var(l)$. We need to compute all solutions $\sigma$ of $C$ that extend $\tau$. Let $\sigma_0 = \tau$. Since $R$ is quasi-reductive we have $Var(u_1) \subseteq Var(l)$ and $\sigma_0(l) \trianglerighteq \sigma_0(u_1)$. By induction hypothesis $\Delta^*_R(\sigma_0(u_1))$ is finite and computable. So we can compute all matches $\sigma'(v_1) \equiv w, w \in \Delta^*_R(\sigma_0(u_1))$, $\sigma'$ extends $\sigma_0$. Let $\sigma_1$ be such a match, then $\sigma_1$ is a solution of $u_1 \rightarrow v_1$ and $\sigma_1(u_1) \trianglerighteq \sigma_1(v_1)$ and so $\sigma_1(l) \equiv \tau(l) \trianglerighteq \sigma_1(u_2)$. In this way one can compute all solutions $\sigma_i$ of $u_1 \rightarrow v_1, \ldots, u_i \rightarrow v_i$ extending $\tau$, and we have $\sigma_i(u_j) \trianglerighteq \sigma_i(v_j)$ for $j = 1, \ldots, i$, so $\sigma_i(l) \trianglerighteq \sigma_i(u_{i+1})$. For $i = n$ we also have $\tau(l) \equiv \sigma_n(l) \trianglerighteq \sigma_n(r)$.

This proves that the set $\{ s \mid t \rightarrow_R s \}$ is finite and computable and that $\rightarrow_R \subseteq \succ$ holds. So $\Delta^*_R(t)$ is finite and computable, too. □

As a by-product of this proof we get
Corollary 3.1 Let $R$ be a DTRS that is quasi-reductive wrt. $\succ$. If $\sigma(l) \rightarrow_R \sigma(r)$ by $\rho \equiv u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \implies l \rightarrow r$ in $R$ then $\sigma(l) \succ_{st} \sigma(u_i) \supset \sigma(v_i)$ for all $1 \leq i \leq n$. \qed

We now discuss how to prove that a DTRS is quasi-reductive. The first approach is to eliminate in a deterministic rule $\rho \equiv u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \implies l \rightarrow r$ the extra variables by backward substitution and then to apply a test for reductivity on the resulting rule. To do so we define the transformed rule $\overline{\rho}$ of $\rho$ as follows: For $x \in \overline{EVar}(\rho)$ let $\alpha(x)$ be the smallest $i$ such that $x \in Var(v_i)$. We simultaneously define terms $\overline{\tau}_i$ and substitutions $\varphi_i$ by

\begin{align*}
\varphi_1 &= id \\
\varphi_{i+1} &= \{ x \leftarrow \overline{\varphi}_i(x) \mid x \in Var(v_1, \ldots, v_i) \cap EVar(\rho) \} \\
\overline{\tau}_i &= \varphi_i(u_i)
\end{align*}

Definition 3.2 Let $\rho \equiv u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \implies l \rightarrow r$ be a deterministic rule. The backward substituted rule $\overline{\rho}$ is $\overline{\tau}_1 \rightarrow c, \ldots, \overline{\tau}_n \rightarrow c \implies l \rightarrow \overline{\tau}$ where $c$ is a new constant and $\overline{\tau} \equiv \varphi_n+1(r)$.

Lemma 3.1 Let $\succ$ be a reduction ordering. Let $R$ be a DTRS such that for every rule $\rho$ in $R$ and its backward substituted form $\overline{\rho} \equiv \overline{\tau}_1 \rightarrow c, \ldots, \overline{\tau}_n \rightarrow c \implies l \rightarrow \overline{\tau}$ we have

$l \succ_{st} \overline{\tau}_i \text{ for } 1 \leq i \leq n \text{ and } l \succ \overline{\tau}$

then $R$ is quasi-reductive wrt. $\succ$.

Proof: One verifies the conditions in Definition 3.1 by induction on $i$. \qed

Example 3.1

a) $\rho \equiv f(x) \rightarrow \text{pair}(y_1, y_2), y_1 + y_2 \rightarrow y_3 \implies f(s(x)) \rightarrow \text{pair}(y_3, y_2)$.

Backward substitution gives $\overline{\rho} \equiv f(x) \rightarrow c, f(x) + f(x) \rightarrow c \implies f(s(x)) \rightarrow \text{pair}(f(x) + f(x), f(x))$. Let $\succ$ be the RPO with precedence $f \succ \text{pair}, +$. Then $\succ = \succ_{st}$ and $f(s(x)) \succ f(x), f(x) + f(x), \text{pair}(f(x) + f(x), f(x))$.

Hence $\rho$ is quasi-reductive wrt. $\succ$.

b) $\rho \equiv f(x) \rightarrow z \implies f(s(x)) \rightarrow f(z)$.

We have $\overline{\rho} \equiv f(x) \rightarrow c \implies f(s(x)) \rightarrow f(f(x))$. Let $\succ$ be the RPO with precedence $s \succ f$. Then $\rho$ is quasi-reductive wrt. $\succ$.

Notice that for a many-sorted specification backward substitution may result in ill-sorted terms. But most of the standard orderings are defined on the well-sorted and the ill-sorted terms as well and so can be used in Lemma 3.1. This holds for examples for the RPOs, LPOs and the polynomial orderings.

There is a direct approach to extend some standard orderings so that they can be used to compare terms with extra variables and so to prove quasi-reductivity. We explain this for the RPO.

If $\mathcal{J} = \{ u_i \geq v_i \mid i = 1, \ldots, n \}$ is a set of inequations then we denote by $\geq_{\mathcal{J}}$ the smallest quasi-ordering containing $\mathcal{J}$. If $s$ is a term, then $\mathcal{J}(s) = \{ s \geq t \mid t \text{ a subterm of } s \}$ is the set of subterm-inequations defined by $s$. 

6
Definition 3.3 Let $\geq$ be a precedence on $\mathcal{F}$ and $\mathcal{J}$ a set of inequations. Then the RPO $\geq_{\mathcal{J}}$ based on $\geq$ and $\mathcal{J}$ is given by

1. $s \geq_{\mathcal{J}} x$ if $s \geq_{\mathcal{J} \cup \mathcal{J}(s)} x$

2. $s \equiv f(s_1, \ldots, s_n) \geq_{\mathcal{J}} t \equiv g(t_1, \ldots, t_m)$ if $s_i \geq_{\mathcal{J}} t$ for some $i$ or
   
   $f > g$ and $s \not\geq_{\mathcal{J}} t$ for all $j$ or
   $f \cong g$ and $\{s_1, \ldots, s_n\} \not\geq_{\mathcal{J}} \{t_1, \ldots, t_m\}$

Here $\geq_{\mathcal{J}}$ denotes the multiset extension of $\geq_{\mathcal{J}}$ and $\not\geq_{\mathcal{J}}$ denotes the strict part of $\geq_{\mathcal{J}}$, i.e. $s \not\geq_{\mathcal{J}} t$ if $s \geq_{\mathcal{J}} t$, but not $t \geq_{\mathcal{J}} s$.

One easily proves

Lemma 3.2 Let $\succ$ be the RPO based on a precedence $\geq$ and let $\succ_{\mathcal{J}}$ be the RPO based on $\geq$ and $\mathcal{J}$. If $s \geq_{\mathcal{J}} t$ then $\sigma(s) \geq_{\mathcal{J}} \sigma(t)$ for all substitutions $\sigma$ with $\sigma(u) \geq_{\mathcal{J}} \sigma(v)$ for all $u \geq v$ in $\mathcal{J}$. □

Let $\rho \equiv u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \equiv l \rightarrow r$ be a rule, let $\mathcal{J}_i = \{u_i \geq v_i | i = 1, \ldots, j - 1\}$ and let $\geq$ be a precedence on $\mathcal{F}$ and let $\succ$ (resp. $\succ_{\mathcal{J}}$) be the RPO based on $\geq$ (and $\mathcal{J}$). We say that $\rho$ is compatible with $\succ$ if there are terms $t, t', t_i, t'_i$ such that

$$l \geq_{\mathcal{J}} t_i \succ t'_i \geq_{\mathcal{J}} u_i \quad \text{for } i = 1, \ldots, n$$

$$l \geq_{\mathcal{J}} t \succ t' \geq_{\mathcal{J}} r$$

Now Lemma 3.2 immediately gives the following generalization of Lemma 3.1.

Theorem 3.2 Let $R$ be a DTRS and $\succ$ an RPO. If every rule in $R$ is compatible with $\succ$ then $R$ is quasi-reductive wrt. $\succ$. □

Example 3.2

$R$: $f(x) \rightarrow f(s(y)) \Rightarrow f(s(x)) \rightarrow f(s(y))$

We have $f(s(s(x))) \not\geq_{R} f(s(x))$, so $\rightarrow_{R}$ is not empty.

Trying backward substitutions we have to prove $f(s(x)) \succ f(x)$ and $f(s(x)) \succ f(f(x)))$ which holds for no reduction ordering. Applying Theorem 3.2 we have to prove with $\mathcal{J} = \{f(x) \geq f(s(y))\}$

$$f(s(x)) \succ f(x) \quad \text{and} \quad f(s(x)) \succ f(x) \geq_{\mathcal{J}} f(s(y))$$

This holds for the RPO based on the empty precedence.

For another method to prove quasi-reductivity we refer to [GW92]. For a method to decide whether $R$ is quasi-reductive wrt. to a given LPO we refer to [Co90].
4 Confluence of a DTRS

We study under which conditions a DTRS $R$ is confluent. We assume that $R$ is a quasi-reductive. In this case $\rightarrow_R$ is terminating and so it is sufficient to prove local confluence. The criterion to be developed for proving local confluence is based on critical pairs. We start with examples to demonstrate the problems arising from extra variables.

Example 4.1

a) $R :$
\[
\begin{align*}
0 + y & \rightarrow y \\
(x + y) + y & \rightarrow x + s(y) \\
x + y & \rightarrow z + z' \implies f(x, y) \rightarrow z
\end{align*}
\]
We have $f(s(0), 0) \rightarrow_R s(0)$ and $f(s(0), 0) \rightarrow 0$, but not $s(0) \downarrow_R 0$. This example shows that a critical pair resulting from overlapping a rule with itself at top-level may be harmful. We call such a critical pair improper.

b) $R :$
\[
\begin{align*}
a & \rightarrow c \\
g(a) & \rightarrow h(b) \\
h(b) & \rightarrow g(c) \\
g(x) & \rightarrow h(z) \implies f(x) \rightarrow z
\end{align*}
\]
We have $f(c) \leftarrow_R f(a) \rightarrow_R b$ but not $f(c) \downarrow_R b$. This example shows that variable overlappings may be harmful.

Notice that in both examples $R$ is a quasi-reductive DTRS. Since we do not want to consider variable overlappings and improper critical pairs we have to look for additional conditions that make them harmless.

Definition 4.1 Let $R$ be a DTRS.

a) A term $v$ is strongly irreducible wrt. $R$ if $\sigma(v)$ is irreducible for every irreducible substitution $\sigma$.

b) $R$ is called strongly deterministic if for every rule $u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \implies l \rightarrow r$ in $R$ each $v_i$ is strongly irreducible wrt. $R$.

Notice that both DTRSs in Example 4.1 are not strongly deterministic. The following system $R$ for computing the Fibonacci numbers is strongly deterministic.

Example 4.2

\[
R : \\
\begin{align*}
fib(x) & \rightarrow pair(y_2, y_1), y_1 + y_2 & \rightarrow y_3 \implies fib(s(x)) & \rightarrow pair(y_3, y_2)
\end{align*}
\]

Definition 4.2 Let $R$ be a DTRS and $C_1 \implies l_1 \rightarrow r_1$ and $C_2 \implies l_2 \rightarrow r_2$ be rules in $R$ that have no variables in common. Let $p \in O(l_1)$ such that $\sigma = mgu(l_2, l_1/p)$ exists. Then
\[
\sigma(C_1), \sigma(C_2) \implies \sigma(l_1[r_2]_p) = \sigma(r_1)
\]

8
is a critical pair. It is called improper if the rules differ only by a variable renaming and 
\( l_1 \equiv l_1/p \), otherwise it is called proper. Let \( CP(R) \) denote the set of proper critical pairs that 
can be built by pairs of rules in \( R \).

A critical pair \( C \Rightarrow s = t \) resulting from \( C_1 \Rightarrow l_1 \rightarrow r_1 \) and \( C_2 \Rightarrow l_2 \rightarrow r_2 \) is joinable if 
\( \tau(s) \mid_R \tau(t) \) for each solution \( \tau \) of \( C \) wrt. \( R \) and \( \text{Var}(l_1, l_2) \).

Now we prove that a strongly deterministic and quasi-reductive DTRS is confluent if all 
proper critical pairs are joinable. Note that there are two problems related to this result: (i) 
Given a term \( v \), is it strongly irreducible? (ii) Given a conditional equation \( C \Rightarrow s = t \), 
is it joinable? Unfortunately, both of these problems are undecidable for a deterministic 
and quasi-reductive \( R \). But we will develop tools to prove that \( v \) is strongly irreducible and 
\( C \Rightarrow s = t \) is joinable wrt. \( R \).

**Theorem 4.1** Let \( R \) be a DTRS that is strongly deterministic and quasi-reductive wrt. \( \succcurlyeq \). 
\( R \) is confluent iff all critical pairs in \( CP(R) \) are joinable.

**Proof:** Clearly, if \( R \) is confluent then all critical pairs in \( CP(R) \) are joinable. So we now assume that 
all critical pairs in \( CP(R) \) are joinable and prove by induction on \( \succcurlyeq \): If \( t' \xrightarrow{\sigma} 
 t \xrightarrow{\tau} t'' \) then \( t' \mid_R t'' \).

If \( t' \equiv t \) or \( t'' \equiv t' \) then \( t' \mid_R t'' \) holds. So assume \( t' \xrightarrow{\sigma} t_1 \xrightarrow{\tau} t_2 \xrightarrow{\sigma} t'' \). We will 
prove \( t_1 \mid_R t_2 \), then an inductive argument easily gives \( t' \mid_R t'' \).

Assume 
\[
\begin{align*}
t & \xrightarrow{R} t_1 & \text{using } C_1 \Rightarrow l_1 \rightarrow r_1, \sigma_1 , \text{ position } q \text{ in } t \\
t & \xrightarrow{R} t_2 & \text{using } C_2 \Rightarrow l_2 \rightarrow r_2, \sigma_2 , \text{ position } p \text{ in } t
\end{align*}
\]

If the \( t/p \) and \( t/q \) are disjoint subterms of \( t \) then \( t_1 \mid_R t_2 \) trivially holds. So we may assume 
that \( t/p \) is a subterm of \( t/q \). If \( t \triangleright t/q \), then \( t \succcurlyeq t/q \) and we have \( t_1 \mid_R t_2 \) by induction hypothesis on \( t/q \). So we assume \( t \equiv t/q \). 
Then we have \( t \equiv \sigma_1(l_1) \) and \( t/p \equiv \sigma_2(l_2) \). There 
are two cases: (a) \( p \in O(l_1) \) and (b) \( p \) is a position in \( l_1 \) with \( l_1/p \) a variable or \( p \) is not a position in \( l_1 \).

(a) : In this case there is a critical pair \( C \Rightarrow s_1 = s_2 \) and a substitution \( \tau \) such that 
\( t_1 \equiv \tau(s_1) \) and \( t_2 \equiv \tau(s_2) \) and \( \tau \) is a solution of \( C \) wrt. \( R \) and \( \text{Var}(l_1, l_2) \). If this critical 
pair is proper then it is in \( CP(R) \) and hence joinable. This gives \( t_1 \mid_R t_2 \). So assume 
that this critical pair is improper. Then \( t \equiv \sigma_1(l_1) \equiv \sigma_2(l_2) \) and we may assume that 
\( C_1 \Rightarrow l_1 \rightarrow r_1 \) and \( C_2 \Rightarrow l_2 \rightarrow r_2 \) are identical, i.e. \( C_i \Rightarrow l_i \rightarrow r_i \equiv C \equiv l \rightarrow r \) for 
\( i = 1, 2 \). We have \( \sigma_1(x) \equiv \sigma_2(x) \) for all \( x \in \text{Var}(l) \) and we will prove \( \sigma_1(x) \mid_R \sigma_2(x) \) for all 
\( x \in \text{Var}(C \Rightarrow l \rightarrow r) \). Since \( t_1 \equiv \sigma_1(r) \) and \( t_2 \equiv \sigma_2(r) \) this will prove \( t_1 \mid_R t_2 \).

Let \( C = u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \) and let \( \sigma'_1, \sigma'_2 \) be irreducible substitutions such that \( \sigma'_i(x) \xrightarrow{R} \sigma'_i(x) \) for \( i = 1, 2 \) and all \( x \in \mathcal{EVar}(C \Rightarrow l \rightarrow r) \). It is enough to prove that \( \sigma'_1(x) \equiv \sigma'_2(x) \) for all 
\( x \in \mathcal{EVar}(C \Rightarrow l \rightarrow r) \). If \( x \in \text{Var}(u_1 \rightarrow v_1) \) then \( x \in \text{Var}(v_1) \) since \( \text{Var}(u_1) \subseteq \text{Var}(l) \). We have 
\( \sigma'_1(v_1) \xrightarrow{\sigma_1(u_1)} \sigma'_2(u_1) \xrightarrow{\sigma_2(u_1)} \sigma'_2(v_1) \) and \( \sigma'_1(v_1) \) is irreducible since \( \sigma'_1 \) is 
irreducible. (Here we need that \( R \) is strongly deterministic and hence the \( v_i \) are strongly 
irreducible.) Since \( t \succcurlyeq \sigma_1(u_1) \) we have \( \sigma'_1(v_1) \mid_R \sigma'_2(v_1) \) by induction hypothesis on \( \sigma_1(u_1) \). 
This gives \( \sigma'_1(v_1) \equiv \sigma'_2(v_1) \) and hence \( \sigma'_1(x) \equiv \sigma'_2(x) \). Now assume \( \sigma'_1(x) \equiv \sigma'_2(x) \) for all 
\( x \in \text{Var}(u_1 \rightarrow v_1, \ldots, u_i \rightarrow v_i) \) \( \text{Var}(l) \), we have to prove \( \sigma'_1(x) \equiv \sigma'_2(x) \) for all \( x \in \text{Var}(u_{i+1} \rightarrow 
 v_{i+1}) \) \( \text{Var}(l) \). If \( x \in \text{Var}(u_i \rightarrow v_i) \) then this is trivial since \( C \Rightarrow l \rightarrow r \) is deterministic. So let 
\( x \in \text{Var}(v_{i+1}) \). We have \( s_0 \) in the following picture since \( \sigma_1(y) \mid_R \sigma_2(y) \) for all \( y \in \text{Var}(u_{i+1}) \).
The term $s_1$ exists by induction hypothesis on $\sigma_1(u_{i+1})$ since $t \triangleright_{st} \sigma_1(u_{i+1})$, and $s_2$ exists by induction hypothesis on $\sigma_2(u_{i+1})$. This proves $\sigma'(v_{i+1}) \downarrow_R \sigma'_2(v_{i+1})$ and now $\sigma'_1(x) \equiv \sigma'_2(x)$ follows as above.

$(\beta)$: In this case there is a variable $x \in \text{Var}(l_1)$ such that $\sigma_2(x) \rightarrow_R t_0$ with $C_2 \Rightarrow l_2 \rightarrow t_2$ and $\sigma_2$. Define $\tau$ to be the substitution $\tau(y) \equiv \sigma_2(y)$ if $y \not\equiv x$ and $\tau(x) \equiv t_0$. Let $\tau'$ be an irreducible substitution with $\tau(y) \rightarrow_R \tau'(y)$ for all $y$. Then we have

$$
t \equiv \sigma_1(l_1) \rightarrow_R t_1 \equiv \sigma_1(r_1) \rightarrow_R \tau(r_1) \rightarrow_R \tau'(r_1)
$$

$$(\text{Here we assume that } t \text{ and } C_1 \Rightarrow l_1 \rightarrow r_1 \text{ have no variables in common}). \text{ We prove that } \tau' \text{ is a solution of } C_1 \text{ wrt. } R \text{ and } \text{Var}(l_1). \text{ Then we have } \tau'(l_1) \rightarrow_R \tau'(r_1) \text{ and so } t_1 \downarrow_R t_2.$$

Let $C_1 = u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n$. We know that $\sigma_1(u_i) \rightarrow_R \sigma_1(v_i)$ and have to prove $\tau'(u_i) \rightarrow_R \tau'(v_i)$. We have $\tau'(u_i) \leftarrow_R \tau'(v_i) \leftarrow_R \sigma_1(u_i) \rightarrow_R \tau'(v_i)$. By induction hypothesis on $\sigma_1(u_i)$ – notice that $t \triangleright_{st} \sigma_1(u_i)$ holds by Corollary 3.3 – we have $\tau'(u_i) \downarrow_R \tau'(v_i)$ and hence $\tau'(u_i) \rightarrow_R \tau'(v_i)$ since $\tau'(v_i)$ is irreducible. So $\tau'$ is indeed a solution of $C_1$ wrt. $R$ and $\text{Var}(l_1)$. \hfill \Box

As mentioned above, it is undecidable whether a DTRS is strongly deterministic. But there is a sufficient condition that is easily testable.

**Definition 4.3** Let $R$ be a DTRS
a) A term $v$ is absolutely irreducible wrt. $R$ if for all $p \in O(v)$ and each rule $C \Rightarrow l \rightarrow r$ in $R \upharpoonright p$ and $l$ are not unifiable.

b) $R$ is absolutely deterministic if for every rule $u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \Rightarrow l \rightarrow r$ in $R$ each $v_i$ is absolutely irreducible wrt. $R$.

In many applications a DTRS is used to define functions over 'free constructors'. If $R$ is such a system and all right-hand sides of conditions in $R$ are constructor terms then $R$ is absolutely deterministic.

**Lemma 4.1** Let $R$ be a DTRS.

a) If $v$ is absolutely irreducible wrt. $R$ then $v$ is strongly irreducible wrt. $R$. 

10
b) If $R$ is absolutely deterministic then $R$ is strongly deterministic.
c) It is undecidable whether a quasi-reductive DTRS is strongly deterministic.

Proof:
a) Let $\sigma$ be an irreducible substitution. If $\sigma(v)$ is reducible then there is a position $p \in O(v)$ and a rule $\mathcal{C} \Rightarrow l \rightarrow r$ in $R$ such that $l$ matches $\sigma(v/p)$, so $l$ and $v/p$ are unifiable. This is impossible if $v$ is absolutely irreducible.
b) This follows from a).
c) We reduce Post’s Correspondence Problem (PCP) to our problem. Let $\Sigma = \{\alpha_1, \ldots, \alpha_n\}$ be an alphabet and $A = a_1, \ldots, a_n$ and $B = b_1, \ldots, b_n$ two lists of words over $\Sigma$. Then

$$PCP(A, B) \text{ iff } a_i a_{i_1} \ldots a_{i_k} \equiv b_i b_{i_1} \ldots b_{i_k} \text{ for some } 1 \leq i_j \leq n, \ j = 1, \ldots, n.$$  

By abuse of notation we identify the letters $\alpha_i$ with unary function symbols $\alpha_i(x)$, then the words $a_j$ and $b_j$ become terms $a_j(x)$ and $b_j(x)$, respectively. We need a new constant 0 and new function symbols $f, g, h, h'$ and use lists over $\{1, \ldots, n\}$. Let

$$R : \begin{align*}
f(nil) & \rightarrow 0 
g(nil) & \rightarrow 0 
f(i, l) & \rightarrow a_i(f(l)) \quad g(i, l) \rightarrow b_i(g(l)) \quad 1 \leq i \leq n 
eq 1 \leq i \leq n 
eq \text{true} 
eq \text{true} 
h(l) & \rightarrow h(l) \quad h'(l) \rightarrow l \quad 1 \leq i \leq n \end{align*}$$

Let $R_0$ consist of the rules in $R$ except the last one. Then $v \equiv h(l)$ is not strongly irreducible wrt. $R_0$ ifff $PCP(A, B)$ holds, so $R$ is strongly deterministic ifff $PCP(A, B)$ does not hold. Notice that $R$ is a quasi-reductive DTRS. Since $PCP$ is undecidable, part c) of the Lemma is proved.

We now develop a sufficient criterion for confluence of a quasi-reductive and strongly deterministic DTRS. It is based on contextual rewriting. We use here a more restrictive version of contextual rewriting than that used in [BG89]. It is easier to implement and results in easier proofs.

Let $C = \{u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n\}$ be a set of oriented equations, called here a context. We denote by $\overline{C}$ its skolemized form, i.e., $\overline{C}$ results from $C$ by replacing each variable $x$ by a new constant $\overline{x}$. If $t$ is a term, then $\overline{t}$ results from $t$ by replacing each $x \in \text{Var}(C)$ by the constant $\overline{x}$. We write $s \rightarrow_{R, C} t$ if $\overline{s} \rightarrow_{R \cup \overline{C}} \overline{t}$. Obviously, we have

**Lemma 4.2** If $s \rightarrow_{R, C} t$ then $\sigma(s) \rightarrow_{R} \sigma(t)$ for every solution $\sigma$ of $C$. 

**Definition 4.4** Let $R$ be a DTRS that is quasi-reductive wrt. $\succ$ and let $C \rightarrow s = t$ be a critical pair resulting from $C_i \Rightarrow l_i \rightarrow r_i$ for $i = 1, 2$ and $\sigma = \text{mgu}(l_1/p, l_2)$. We call $C \Rightarrow s = t$ unfeasible if there are terms $t_0, t_1, t_2$ such that $\sigma(t_1) \succ_{st} t_0$, $t_0 \rightarrow_{R, C} t_1$, $t_0 \rightarrow_{R, C} t_2$ and $t_1, t_2$ are not unifiable and strongly irreducible. We call $C \Rightarrow s = t$ context-joinable if there is some $t_0$ such that $s \rightarrow_{R, C} t_0$, $t \rightarrow_{R, C} t_0$.

Note that in the definition of an unfeasible critical pair $C \Rightarrow s = t$ we have $\sigma(l_1) \succ u$ if $u \rightarrow v$ in $C$ and $\text{Var}(u) \subseteq \text{Var}(\sigma(l_1))$. So we may choose $t_0$ to be any such term $u$. In many cases a quasi-reductive and strongly deterministic DTRS can be proved to be confluent by the following Theorem.
**Theorem 4.2** Let $R$ be a DTRS that is quasi-reductive wrt. $\rightarrow$ and strongly deterministic. If every critical pair in $CP(R)$ is either unfeasible or context-joinable then $R$ is confluent.

**Proof:** We repeat the proof of Theorem 4.1. The only point we have to consider is the first case in (α): Let $C \Rightarrow s_1 = s_2$ be a proper critical pair resulting from $C_i \Rightarrow l_i \rightarrow r_i, i = 1, 2,$ and $\sigma = mgu(l_1/p, l_2)$. There is a solution $\tau$ of $C$ such that $t \equiv \tau(\sigma(l_1))$ and $t_1 \equiv \tau(s_1), t_2 \equiv \tau(s_2)$. By induction hypothesis on $t$ we may assume: If $s' \rightarrow_R s \rightarrow_R s''$ and $\tau(\sigma(l_1)) \rightarrow_{st} s$ then $s' \rightarrow_R s''$. Then we have to prove $t_1 \rightarrow_R t_2$.

$C \Rightarrow s_1 = s_2$ is not unfeasible: Otherwise there are $t_0, t'_0, t''_0$ such that $\sigma(l_1) \rightarrow_{st} t_0, t_0 \rightarrow_R t'_0, t'_0 \rightarrow_R t''_0$ and $t_0, t'_0, t''_0$ are not unifiable and strongly irreducible. Since $\tau$ is a solution of $C$ we have by Lemma 4.2 that $\tau(\sigma(l_1)) \rightarrow_{st} \tau(t_0), \tau(t_0) \rightarrow_R \tau(t'_0)$ and $\tau(t_0) \rightarrow_R \tau(t''_0)$. Let $\mu$ be an irreducible substitution such that $\tau(x) \rightarrow_R \mu(x)$ for all $x$. Then $\tau(t_0) \rightarrow_R \mu(t'_0)$ and $\tau(t_0) \rightarrow_R \mu(t''_0)$ and $\mu(t'_0) \neq \mu(t''_0)$. By induction hypothesis on $\tau(t_0)$ we have $\mu(t'_0) \not\rightarrow_R \mu(t''_0)$.

So $C \Rightarrow s_1 = s_2$ is context-joinable. Since $\tau$ is a solution of $C$ we have $t_1 \equiv \tau(s_1) \rightarrow_R \tau(s_2) \equiv t_2$ by Lemma 4.2.

Let $C \Rightarrow s = t$ be a critical pair of some $R$. If $s \equiv t$ then it is called trivial. A trivial critical pair is always context-joinable. If $C$ contains $u \rightarrow a$ and $u \rightarrow b$, where $a$ and $b$ are distinct irreducible constants, then $C \Rightarrow s = t$ is unfeasible. But there are less trivial examples where Theorem 4.2 is applicable.

**Example 4.3** (see [BG89])
We specify the Quicksort-algorithm

$R :$

<td>$\text{sort}(x.l) \rightarrow \text{app}(\text{sort}(l_1), x.\text{sort}(l_2))$</td>
</tr>
</tbody>
</table>

There is only one proper critical pair, it is $C \Rightarrow \text{pair}(y.l_1, l_2) = \text{pair}(l_1, y.l_2)$ with $C \equiv x \leq y \rightarrow \text{true}, \text{split}(x, l) \rightarrow \text{pair}(l_1, l_2), x \leq y \rightarrow \text{false}, \text{split}(x, l) \rightarrow \text{pair}(l'_1, l'_2)$ and it results from rules (7) and (8). Since $C$ contains $x \leq y \rightarrow \text{false}$ and $x \leq y \rightarrow \text{true}$, this critical pair is unfeasible. $R$ is strongly deterministic and $R$ is quasi-reductive wrt. to a semantic path ordering [St93], [Ge92]. So we have a simple proof that $R$ is confluent.

5 On the descriptive power of $\rightarrow_R$

Any conditional term rewriting system $R$ can naturally be regarded as a set of conditional equations. So the $R$-equality $=_R$ is well-defined (for details see below). If $R$ is a standard
system without extra variables then the following fact is well-known: If \( R \) is confluent then \( \rightarrow^*_{R} = =_R \). We prove a similar result for strongly deterministic systems. We start with an example to demonstrate the problems arising from directed conditions.

**Example 5.1**

\[
R: \quad g(x) \rightarrow h(x) \\
\quad h(x) \rightarrow g(y) \quad \Rightarrow \quad f(x) \rightarrow y
\]

Let \( \succ \) be the RPO with precedence \( f \succ g \succ h \). Then \( R \) is quasi-reductive wrt. \( \succ \). We have \( CP(R) = \emptyset \), so \( R \) is terminating and confluent. We have \( f(x) =_R x \) but not \( f(x) \mid R x \). So \( \rightarrow^*_{R} \) is properly included in \( =_R \). Notice that \( R \) is not strongly deterministic.

We now formally define \( =_R \).

A conditional equation over a signature \( \text{sig} = (S, \mathcal{F}, \tau) \) is a formula of the form

\[
u_1 = v_1, \ldots, u_n = v_n \implies s = t
\]

A conditional equational system \( E \) is a set of conditional equations. We are going to define \( =_E \).

Let \( E \) be a conditional equational system and let \( G \) be a set of unconditional equations. We first define an inference system depending on \( E \) and \( G \). It consists of the following five rules:

| Reflexivity | \( \vdash t = t \) |
| Symmetry    | \( t_1 = t_2 \vdash t_2 = t_1 \) |
| Transitivity| \( t_1 = t_2, t_2 = t_3 \vdash t_1 = t_3 \) |
| Congruence  | \( t_1 = s_1, \ldots, t_n = s_n \vdash f(t_1, \ldots, t_n) = f(s_1, \ldots, s_n) \) |
| E-Application| \( \sigma(u_1) = \sigma(v_1), \ldots, \sigma(u_n) = \sigma(v_n) \vdash \sigma(s) = \sigma(t) \) |

We write \( G \vdash_E u = v \) if \( u = v \) can be deduced by this inference system.

Next we define an infinite sequence \( (E_i)_{i \geq 0} \) of unconditional equational systems as an approximation of \( E \):

\[
E_0 = \{ u = v \mid \emptyset \vdash_E u = v \} \\
E_{i+1} = E_i \cup \{ u = v \mid E_i \vdash_E u = v \}
\]

Now

\[
u =_E v \quad \text{iff} \quad u = v \quad \text{in some} \quad E_i, i \geq 0.
\]

The relevance of this definition is based on Birkhoff’s Theorem: \( u =_E v \) iff \( u = v \) holds in every model of \( E \).

Now let \( R \) be a DTRS. We associate to \( R \) the conditional equational system

\[
E(R) = \{ u_1 = v_1, \ldots, u_n = v_n \implies l = r \mid u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \implies l \rightarrow r \quad \text{in} \quad R \}
\]

and simply write \( u =_R v \) instead of \( u =_{E(R)} v \).
Theorem 5.1 Let R be strongly deterministic, terminating and confluent. Then $s \xrightarrow{*} R t$ iff $s \rightarrow R t$.

Proof: Let $(E_i)_{i \geq 0}$ be the approximation of $E(R)$ and $=i = =E_i$. Let $(R_i)_{i \geq 0}$ be the approximation of $R$ and $\rightarrow i = \rightarrow R_i$.

a) $s \xrightarrow{*} R t$ implies $s \rightarrow R t$: Induction on $i$ proves $\rightarrow i \subseteq =i$. This gives $\rightarrow R \subseteq =R$ and $\xrightarrow{*} R \subseteq =R$.

b) $s \rightarrow R t$ implies $s \xrightarrow{*} R t$: We prove by induction on $i$ that $=i \subseteq \xrightarrow{*} R$ for all $i \geq 0$. Then $=R \subseteq \xrightarrow{*} R$ immediately follows.

For $i = 0$ we trivially have $=0 = \xrightarrow{*} 0 \subseteq \xrightarrow{*} R$. Let $i > 0$. Then $=i$ is the smallest congruence relation with $=i-1 \subseteq =i$ and $\sigma(l) = \sigma(r)$ whenever $\rho \equiv u_1 \rightarrow \ldots v_n \rightarrow \sigma(r)$ is in $R$ and $\sigma(u_j) = \sigma(v_j)$ for $1 \leq j \leq n$. Also $\xrightarrow{*} R$ is a congruence relation. So it is enough to prove $\sigma(l) \xrightarrow{*} R \sigma(r)$ if $\sigma(u_j) = \sigma(v_j)$ for $1 \leq j \leq n$. Let $\sigma'$ be the irreducible substitution with $\sigma(x) \xrightarrow{*} R \sigma'(x)$ for all $x \in \text{Var}(\rho)$. By induction hypothesis we have $\sigma(u_j) \xrightarrow{*} R \sigma(v_j)$ and hence $\sigma'(u_j) \xrightarrow{*} R \sigma'(v_j)$. Since $\rightarrow R$ is confluent and $\sigma'(v_j)$ is irreducible we get $\sigma'(u_j) \xrightarrow{*} R \sigma'(v_j)$ for $1 \leq j \leq n$. This implies $\sigma'(l) \rightarrow R \sigma'(r)$ and hence we have $\sigma(l) \xrightarrow{*} R \sigma(r)$.

We call R logical if $\xrightarrow{*} R$ equals $= R$. By Theorem 5.1, R is logical if R is strongly deterministic, quasi-reductive and confluent. For some applications quasi-reductivity is a requirement that is too hard. The rewrite relation $\rightarrow R$ may be computable but not terminating. So the question arises whether Theorem 5.1 holds true if R is allowed to be non-terminating. The proof of Theorem 5.1 shows that the answer is 'yes' if R is weakly terminating, i.e. for every t there is an irreducible term $t'$ such that $t \xrightarrow{*} R t'$. The next example shows that the answer to the question is 'no' in general.

Example 5.2

$R:\ a \rightarrow b \quad f(a) \rightarrow a \quad f'(a) \rightarrow a$

$b \rightarrow a \quad f(b) \rightarrow a \quad f'(b) \rightarrow a$

$f'(x) \rightarrow f(x) \Rightarrow g(x) \rightarrow x$

R is a normal conditional rewrite system in the sense of [D090]. It is strongly deterministic since $f(x)$ is strongly irreducible, but R is not terminating and not absolutely deterministic.

To prove confluence one easily shows by induction on $\vdash$: If $t_1 R \Rightarrow t \Rightarrow R t_2$ then there is a term $s$ with $t_1 \leq_1 R s$ and $t_2 \leq_1 R s$. (Here $\leq_1$ denotes $t \equiv s$ or $t \Rightarrow R s$.) By Lemma 2.5 in [Hu80] this proves that $\rightarrow R$ is indeed confluent. We have $f(a) =_R f'(a)$ and hence $g(a) =_R a$. But $g(a) \nmid R a$ does not hold. So R is not logical.

Now we prove that the result of Theorem 5.1 still holds if the termination assumption is replaced by stronger restrictions on the rules in R.

Theorem 5.2 Let R be a confluent DTRS such that for every rule $u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \Rightarrow l \rightarrow R$ in

$v_i$ is absolutely irreducible and

$\text{Var}(v_i) \cap \text{Var}(u_1, \ldots, u_i) = \emptyset$

for $1 \leq i \leq n$. Then $s \xrightarrow{*} R t$ iff $s =_R t$.

Proof: We repeat the proof of Theorem 5.1. Part a) carries over directly. For b) we have to show:
Claim: If \( \rho \equiv u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \iff l \rightarrow r \) in \( R \) and \( \sigma(u_j) \not\rightarrow_R \sigma(v_j) \) then there is a \( \sigma' \) such that \( \sigma'(u_j) \not\rightarrow_R \sigma'(v_j) \) for \( 1 \leq j \leq n \) and \( \sigma(x) \not\rightarrow_R \sigma'(x) \) for all \( x \in \text{Var}(\rho) \).

From this claim we get \( \sigma'(l) \not\rightarrow_R \sigma'(r) \) and \( \sigma(l) \not\rightarrow_R \sigma(v) \). Then the proof of Theorem 5.1 can be carried over.

Let the assumption of the claim hold true. We will define \( \sigma' \) by induction on \( j \). To do so we need the following fact: If \( v \) is absolutely irreducible and \( \tau(v) \not\rightarrow_R w \) then \( w \not\rightarrow_R \tau'(v) \) and \( \tau(x) \not\rightarrow_R \tau'(x) \) for some substitution \( \tau' \). This fact holds true even if \( v \) is non-linear since \( \not\rightarrow_R \) is confluent. Together with \( \sigma(u_j) \not\rightarrow \sigma(v_j) \) it implies that there are substitutions \( \sigma'_j \) such that \( \sigma(u_j) \not\rightarrow_R \sigma'_j(v_j) \).

We are going to define \( \sigma_1, \ldots, \sigma_n \) such that \( \sigma_j(u_j) \not\rightarrow_R \sigma'_j(v_j) \) for \( 1 \leq i \leq j \) and \( \sigma(x) \not\rightarrow_R \sigma_j(x) \) for \( x \in \text{Var}(u_1, v_1, \ldots, u_j, v_j) \): For \( j = 1 \) we may choose \( \sigma_1 = \sigma'_1 \).

Using \( \sigma_{j-1} \) we now have to define \( \sigma_j \). We have \( \sigma_{j-1}(u_j) \not\rightarrow_R \sigma_j(u_j) \not\rightarrow_R \sigma'_j(v_j) \), so there is \( \sigma'_j \) with \( \sigma_{j-1}(u_j) \not\rightarrow_R \sigma'_j(v_j) \) since \( \not\rightarrow_R \) is confluent and \( v_j \) is absolutely irreducible. If \( x \in \text{Var}(v_j) \cap \text{Var}(v_1, \ldots, v_{j-1}) \) then \( \sigma_{j-1}(x) \not\rightarrow_R \sigma(x) \not\rightarrow_R \sigma'_j(x) \), so \( \sigma_{j-1}(x) \not\rightarrow_R \tau_x \not\rightarrow_R \sigma'_j(x) \) for some \( \tau_x \). Now we define \( \sigma_j \) by

\[
\sigma_j(x) \equiv \begin{cases} 
\sigma_{j-1}(x) & x \not\in \text{Var}(v_j) \\
\sigma''_j(x) & x \in \text{Var}(v_j) - \text{Var}(v_1, \ldots, v_{j-1}) \\
\tau_x & x \in \text{Var}(v_j) \cap \text{Var}(v_1, \ldots, v_{j-1})
\end{cases}
\]

Then \( \sigma_{j-1}(x) \not\rightarrow_R \sigma_j(x) \) for \( x \in \text{Var}(u_1, v_1, \ldots, u_{j-1}, v_{j-1}) \) and \( \sigma(x) \not\rightarrow_R \sigma_j(x) \) for \( x \in \text{Var}(u_1, v_1, \ldots, u_j, v_j) \). We have \( \sigma_j(u_i) \not\rightarrow_R \sigma_j(v_i) \) for \( 1 \leq i < j \), since \( \text{Var}(v_j) \cap \text{Var}(u_1, \ldots, u_j) = \emptyset \) and \( \sigma_j(u_i) \not\rightarrow_R \sigma_j(v_i) \), and we have \( \sigma_j(u_j) \not\rightarrow_R \sigma_j(v_j) \) by construction.

Now choosing \( \sigma' = \sigma_n \) the claim is proved. This finishes the proof of the theorem.

Theorem 5.2 holds if in each rule \( u_1 \rightarrow v_1, \ldots, u_n \rightarrow v_n \iff l \rightarrow r \) the \( v_i \)’s are irreducible constants. One may ask whether the condition \( \text{Var}(v_j) \cap \text{Var}(u_1, \ldots, u_i) = \emptyset \) can be dropped. The following example shows that then the Theorem may not hold, even if the \( v_i \)’s are restricted to be variables. This indicates that conditional rewrite systems are very sensitive according to the introduction of extra-variables.

**Example 5.3**

\( R = b \rightarrow a, a \rightarrow b \)

\( R \) is confluent, absolutely deterministic and not terminating. Taking \( \sigma = \{ z \rightarrow b \} \) one gets \( f(a) = c \). But both terms \( f(a) \) and \( c \) are irreducible, so \( f(a) \not\rightarrow c \) does not hold. Hence \( R \) is not logical. Note that Theorem 5.2 is not applicable to \( R \) only because of \( v_2 \equiv z \in \text{Var}(u_2) = \text{Var}(g(a, z)) \).

### 6 Uniquely terminating well-moded logic programs

We now apply the results of the previous sections to well-moded logic programs.

A logical program is a set of Horn-clauses. Normally such a program is used to describe a search in a search space. In this case no distinction is made between input and output
positions for the predicate symbols. But it has turned out that logic programs are also
widely used to write programs in a functional manner. In this case each predicate symbol
is assigned a fixed 'mode' to distinguish between input and output positions. To compute
with such a moded program one starts with a query such that its input positions are filled
by ground terms. Then, doing logical operations the information sweeps into the output
positions.

So the question arises whether a well-moded logic program is uniquely terminating, i.e.
whether for each input all possible computations stop and give the same result. In this
section we develop means to assure this property.

This problem has been studied earlier by the first author [HA85]. The results presented
here go far about those presented there. For example, we do not restrict to hierarchical
specifications of the logic program. Here we follow the approach of [GW92]. In that paper
only termination of computations in logic programs is studied. Here we are also interested
in guaranteeing uniqueness of the results.

We start with some notations and definitions but we assume that the reader has some knowl-
edge on logic programming and SLD-derivations.

A signature is a quadruple \( \sigma(g_0) = (S, P_0, F_0, \tau_0) \) where \( S \) is a set of sorts, \( F_0 \) is a set of
function symbols, \( P_0 \) is a set of predicate symbols and \( \tau_0 : F_0 \cup P_0 \rightarrow S^+ \) assigns to each
function and predicate symbol its arity. If \( P \in P_0 \) and \( t_1, \ldots, t_n \) are terms then \( P(t_1, \ldots, t_n) \)
is an atom. A Horn-clause is a formula of the form \( A \leftarrow B_1, \ldots, B_m \) where \( m \geq 0 \) and \( A, B_i \)
are atoms. A logic program \( P \) is a set of Horn-clauses. A query is a formula of the form
\( \leftarrow B_1, \ldots, B_m \) where \( m \geq 1 \) and \( B_i \) are atoms.

A logic program \( P \) is moded if for every occurrence of an atom \( A \equiv P(t_1, \ldots, t_n) \) there is a
function \( m_A : \{1, \ldots, n\} \rightarrow \{\text{in}, \text{out}\} \). If \( m_A(i) = \text{in} \) (\( m_A(i) = \text{out} \)) then position \( i \) is called
an input position (output position) of \( A \). A variable \( x \) occurs in an input (output) position in
\( A \) if \( x \in \text{Var}(t_i) \) for some \( i \) with \( m_A(i) = \text{in} \) (\( m_A(i) = \text{out} \)).

To evaluate a moded logic program \( P \) we only consider left-to-right SLD-derivations. They
always select the left-most literal of a query for the next resolution step. So we restrict to
LR-well-moded programs as defined next.

**Definition 6.1** a) Let \( C \equiv A \leftarrow B_1, \ldots, B_m \) be a clause and \( x \in \text{Var}(C) \). The head \( A \) of
\( C \) is called a producer (consumer) of \( x \), if \( x \) occurs in an input (output) position of \( A \). The
body atom \( B_j \) is called a producer (consumer) of \( x \), if \( x \) occurs in an output (input) position of
\( B_j \).

b) The clause \( B_0 \leftarrow B_1, \ldots, B_m \) is called LR-well-moded, if every variable \( x \) in the clause
has a producer \( B_i \) (\( 0 \leq i \leq n \)) such that for every consumer \( B_j \) of \( x \) we have \( i < j \). A logic
program \( P \) is LR-well-moded if every clause in \( P \) is LR-well-moded.

c) A query \( \leftarrow B_1, \ldots, B_m \) is LR-well-moded if every variable \( x \) in the query has a producer
\( B_i \) such that for every consumer \( B_j \) of \( x \) we have \( i < j \).

By this definition, if \( \leftarrow B_1, \ldots, B_m \) is LR-well-moded and \( B_1 \equiv P(t_1, \ldots, t_n) \) then \( t_i \) are
ground terms for all input positions \( i \) of \( B_1 \). One easily proves [GW92]

**Lemma 6.1** Let \( P \) be an LR-well-moded logic program and \( G_0, G_1, \ldots \) a left-to-right SLD-
derivation starting with an LR-well-moded query \( G_0 \). Then all queries \( G_i \) are LR-well-moded,
and the first atom of every non-empty \( G_i \) is ground on all its input positions. \( \Box \).
Now we associate to every logic program \( \mathcal{P} \) over the signature \( \text{sig} = (S, \mathcal{P}_0, \mathcal{F}_0, \tau_0) \) a DTRS \( R(\mathcal{P}) \) over the signature \( \text{sig} = (S, \mathcal{F}, \tau) \). Here \( \mathcal{F} \) consists of the \( f \in \mathcal{F}_0 \) and for each atom \( A \equiv P(t_1, \ldots, t_n) \) with input positions \( i_1, \ldots, i_k \) and output positions \( i_{k+1}, \ldots, i_n \) the two function symbols \( \text{Pin} \) and \( \text{Pout} \). We associate to the atom \( A \equiv P(t_1, \ldots, t_n) \) the rule \( \rho(A) \equiv \text{Pin}(t_{i_1}, \ldots, t_{i_k}) \rightarrow \text{Pout}(t_{i_{k+1}}, \ldots, t_{i_n}) \). We associate to a clause \( C \equiv A \leftarrow B_1, \ldots, B_m \) the rule

\[
\rho(C) \equiv \rho(B_1), \ldots, \rho(B_m) \Rightarrow \rho(A)
\]

and to \( \mathcal{P} \) the system \( R(\mathcal{P}) = \{ \rho(C) \mid C \text{ in } \mathcal{P} \} \).

**Example 6.1**

\( \mathcal{P} : \) \( \text{APP}(\text{nil}, l_2, l_2) \leftarrow \text{APP}(x, l_1, l_2, x, l_3) \leftarrow \text{APP}(l_1, l_2, l_3) \)

\( R(\mathcal{P}) \)

\( \text{APP}(\text{nil}, l_2, l_2) \rightarrow \text{APP}(\text{nil}, l_2, l_1, l_2) \rightarrow \text{APP}(x, l_1, l_2) \rightarrow \text{APP}(x, l_1, l_3) \)

\( \text{APP}(l_1, l_2, l_3) \rightarrow \text{APP}(x, l_1, l_3) \rightarrow \text{APP}(x, l_1, l_2) \)

In both cases \( R(\mathcal{P}) \) is strongly deterministic and quasi-reductive. In case a) \( R(\mathcal{P}) \) is confluent, but in case b) \( R(\mathcal{P}) \) is not confluent.

The following lemma states that \( R(\mathcal{P}) \) is always absolutely deterministic if \( \mathcal{P} \) is LR-well-moded.

**Lemma 6.2**

a) If \( C = A \leftarrow B_1, \ldots, B_m \) is LR-well-moded then \( \rho(C) \) is deterministic.

b) If \( \mathcal{P} \) is LR-well-moded then \( R(\mathcal{P}) \) is absolutely deterministic.

c) If \( \leftarrow B_1, \ldots, B_m \) is an LR-well-moded query and \( \rho(B_1) \equiv \text{Pin}(t_1, \ldots, t_n) \rightarrow \text{Pout}(s_1, \ldots, s_k) \) then all \( t_i \) are ground terms.

**Proof:** a) This follows directly from the definitions.

b) \( R(\mathcal{P}) \) is deterministic by a). If \( u_1 \leftarrow v_1, \ldots, u_n \leftarrow v_n \Rightarrow l \rightarrow r \) is a rule \( R(\mathcal{P}) \) then \( v_i \) is of the form \( \text{Pout}(s_1, \ldots, s_k) \) and \( l \) is of the form \( \text{Pin}(t_1, \ldots, t_n) \). So each \( v_i \) is absolutely irreducible wrt. \( R(\mathcal{P}) \). Hence \( R(\mathcal{P}) \) is absolutely deterministic.

c) This follows from Lemma 6.1. \( \square \)

The following lemma relates computations in \( \mathcal{P} \) to computations in \( R(\mathcal{P}) \). It is proved in [GW92].

**Lemma 6.3** Let \( \mathcal{P} \) be an LR-well-moded logic program such that \( R(\mathcal{P}) \) is quasi-reductive and let \( \leftarrow B \) be an LR-well-moded query. If there is a left-to-right SLD-refutation of \( \leftarrow B \) with computed answer substitution \( \theta \) and \( \rho(B) \equiv \text{Pin}(t_1, \ldots, t_m) \rightarrow \text{Pout}(s_1, \ldots, s_k) \) then

\[
\text{Pin}(t_1, \ldots, t_m) \rightarrow_R \text{Pout}(\theta(s_1), \ldots, \theta(s_k))
\]

\( \square \).
We now come to the main result of this section.

**Definition 6.2** An LR-well-moded logic program $P$ is uniquely terminating if for every LR-well-moded query $\leftarrow B$ every left-to-right SLD-derivation is terminating and every left-to-right SLD-refutation computes the same answer substitution $\theta$.

**Theorem 6.1** Let $P$ be an LR-well-moded logic program such that $R(P)$ is quasi-reductive and every critical pair in $CP(R(P))$ is either unfeasible or context-joinable. Then $P$ is uniquely terminating.

**Proof:** By Theorem 4.5 of [GW92] every left-to-right SLD-derivation starting with an LR-well-moded query $\leftarrow B$ terminates. Since $R(P)$ is strongly deterministic it is confluent by Theorem 4.2. Now the statement follows from Lemma 6.3. \hfill $\Box$

**Example 6.2**

a) The following logic program is intended to compute from a given list $l$ the last element $z$ of $l$ and the list $l'$ resulting from $l$ by eliminating $z$.

$P: \quad P(x,nil,x,nil) \leftarrow$

$P(x,y,l,z,x,l') \leftarrow P(y,l,z,l')$

Translation of $P$ into a rewrite system gives

$R(P):$

$Pin(x,nil) \rightarrow Pout(x,nil)$

$Pin(y,l) \rightarrow Pout(z,l') \Rightarrow P(x,y,l) \rightarrow Pout(z,x,l')$

We prove that $R(P)$ is quasi-reductive by using the backward substitution technique: We have to prove that $Pin(x,y,l) > Pout(Pin(y,l),x,Pin(y,l))$. This holds true for the RPO based on the precedence $Pin > Pout, Pin >$. We have $CP(R(P)) = \emptyset$, so $R(P)$ is confluent and $P$ is uniquely terminating.

b) The following logic program $P$ is intended to compute the greatest common divisor $z$ of the natural numbers $x, y$.

$P: \quad GCD(x,0,x) \leftarrow$

$GCD(0,y,y) \leftarrow$

$GCD(s(x),s(y),z) \leftarrow LESS(x,y,true), SUB(y,x,z_1), GCD(s(x),z_1,z)$

$GCD(s(x),s(y),z) \leftarrow LESS(x,y,false), SUB(x,y,z_1), GCD(z_1,s(y),z)$

$SUB(x,0,x) \leftarrow$

$SUB(s(x),s(y),z) \leftarrow SUB(x,y,z)$

$LESS(x,0,false) \leftarrow$

$LESS(0,s(y),true) \leftarrow$

$LESS(s(x),s(y),u) \leftarrow LESS(x,y,u)$

This gives $R(P)$:
(1) \( GCDin(x, 0) \rightarrow GCDout(x) \)
(2) \( GCDin(0, y) \rightarrow GCDout(y) \)
(3) \( LESSin(x, y) \rightarrow LESSout(true), \)
\( SUBin(y, x) \rightarrow SU Bout(z_1), \)
\( GCDin(s(x), z_1) \rightarrow GCDout(z) \implies GCDin(s(x), s(y)) \rightarrow GCDout(z) \)
(4) \( LESSin(x, y) \rightarrow LESSout(false), \)
\( SUBin(x, y) \rightarrow SU Bout(z_1), \)
\( GCDin(z_1, s(y)) \rightarrow GCDout(z) \implies GCDin(s(x), s(y)) \rightarrow GCDout(z) \)
(5) \( SUBin(x, y) \rightarrow SU Bout(z) \implies SUBin(s(x), s(y)) \rightarrow SU Bout(z) \)
(6) \( LESSin(x, y) \rightarrow LESSout(true) \)
(7) \( LESSin(0, s(y)) \rightarrow LESSout(false) \)
(8) \( LESSin(s(x), s(y)) \rightarrow LESSout(u) \)
(9) \( LESSin(x, y) \rightarrow LESSout(u) \implies LESSin(s(x), s(y)) \rightarrow LESSout(u) \)

One can prove that \( R(P) \) is quasi-reductive using backward substitution and an appropriate semantic path ordering [St93]. There is only one proper critical pair \( C \implies GCDout(z) = GCDout(z') \) generated by the third and fourth rule in \( R(P) \). Here \( C \) contains \( LESSin(x, y) \rightarrow LESSout(true) \) and \( LESSin(x, y) \rightarrow LESSout(false) \), so this critical pair is unfeasible. Hence \( R(P) \) is confluent and \( P \) is uniquely terminating.
