Abstract

We propose and study a strongly coupled PDE-ODE-ODE system modeling cancer cell invasion through a tissue network under the go-or-grow hypothesis asserting that cancer cells can either move or proliferate. Hence our setting features two interacting cell populations with their mutual transitions and involves tissue-dependent degenerate diffusion and haptotaxis for the moving subpopulation. The proliferating cells and the tissue evolution are characterized by way of ODEs for the respective densities. We prove the global existence of weak solutions and illustrate the model behaviour by numerical simulations in a two-dimensional setting.

Keywords: cancer cell invasion; degenerate diffusion; global existence; go-or-grow dichotomy; haptotaxis; parabolic system; weak solution.

1 Introduction

One of the essential characteristics of a tumor is its heterogeneity. The cells forming the neoplastic tissue often have different phenotypes, morphologies, and functions, and can switch between these in response to intra- and/or extracellular influences like e.g., genetic change, acidity of the peritumoral region, availability of nutrients and/or space, applied therapeutic agents etc., see e.g. [25, 30, 33]. Tumor heterogeneity is tightly connected to compromised treatment response [15, 22] and is already manifested at the migrating stage of tumor development. Indeed, one of the main features of tumor development and invasion is the ability of cancer cells to migrate and spread into the normal tissue, whereby they experience different migratory phenotypes (e.g., amoeboid vs. mesenchymal). Furthermore, experimental evidence revealed that several types of tumor cells (including glioma, breast cancer cells, and melanoma) defer their proliferation while migrating and vice versa [18, 20, 24, 41], corresponding to the so-called go-or-grow dichotomy. The differentiated response of tumor cells to treatment is a main cause of radio- and chemotherapeutical failure; indeed, it is largely accepted that cells with a highly proliferating phenotype are more sensitive to therapy, whereas the migratory phenotype is attended by reduced treatment sensitivity, see e.g., [27, 34, 37] and the references therein.

Motivated by the above mentioned facts we propose in this paper a model for tumor cell invasion in which we account for the go-or-grow hypothesis and distinguish between migrating and proliferating (hence non-moving) cells. Several continuum mathematical models relying on the go-or-grow behavior of tumor cells and explicitly accounting for the two subpopulations of migrating and proliferating cells, respectively, have been considered e.g., in [16, 35] and featured reaction-(cross-)diffusion-(chemotaxis) equations. Using a two-component continuous-time random walk along with a probabilistic approach based thereupon and involving switching with exponentially distributed waiting times between the proliferation and migration phenotypes, Fedotov & Iomin deduced in [14] an ODE-PDE system for the macroscopic dynamics of the two types of cancer cell densities, supporting the idea of tumor cells subdiffusivity instead of the more common Fickian diffusivity. In [8] Chauviere et al. used a mesoscopic description of the two cell subpopulations to deduce by an appropriate scaling a system of two coupled reaction-diffusion equations for their macrolevel behavior. Still in that context, starting from mesoscopic equations for the two cell subpopulations and coupling them with subcellular level dynamics in [11, 23] the authors obtained by parabolic scalings macroscopic equations characterizing the evolution of the overall tumor burden for a glioma invasion model. The resulting equations carried in their coefficients the information from the lower
modeling scales (both subcellular and mesoscopic) and allowed DTI-based predictions about the tumor extent and simulation-based therapy outcomes. The haptotaxis term obtained in those macroscopic equations was a direct consequence of accounting for the subcellular receptor binding dynamics in the mesoscale evolution of the cancer cell densities. By using the equilibrium of fluxes and some ideas from [31, 32], in [38] was introduced a multiscale model for macroscopic tumor invasion and development complying to the go-or-grow dichotomy and including subcellular dynamics of receptor binding to fibers of the underlying extracellular matrix (ECM). Our model in this paper extends in a certain way the previous setting in [38] by allowing the diffusion coefficient to degenerate and by paying increased attention to the haptotactic sensitivity function; however, neither therapy effects nor multiscale issues are addressed here.

While there is a vast literature concerning the mathematical analysis of reaction-diffusion-taxis equations, problems with degenerate diffusion and taxis have been less investigated. However, during the last decade many such references became available; they describe the dynamics of a cell population in response to a chemoattractant [10, 26, 40], moving up the gradient of an insoluble signal (haptotaxis) [42, 44], or performing both chemotaxis and haptotaxis [28, 39, 43]. Thereby, the type of degeneracy is a particularly relevant feature for the difficulty of the problem, especially for systems coupling ODEs with PDEs, as is the case when considering haptotaxis. In [28, 39, 43] the diffusion coefficients depend nonlinearly on the solution and the tactic sensitivities are constants. For these problems the global well posedness was obtained, along with boundedness properties of the solutions. The model proposed in [44] involves a diffusion coefficient which can degenerate due to each of the solution components (density of cells and of ECM fibers, respectively); moreover, the haptotactic sensitivity is a nonlinear function of the ECM density. The 1D model in [42] was motivated by the deduction of macroscopic equations from a mesoscopic setting for brain tumor invasion also accounting for subcellular dynamics; it features a reaction-diffusion-transport-haptotaxis equation for the tumor cell density coupled with an ODE for the density of tissue fibers. The strong degeneracy of the diffusion and haptotaxis coefficients is attained by way of a function only depending on the position and not on the solution itself. Whereas the global existence of weak solutions was shown for these models, the boundedness and uniqueness issues remain open. The same applies to the mathematical setting considered in this work and presented in detail in the following Section 2. The rest of the paper is organized as follows: Section 3 introduces some basic notations, Section 4 settles the problem and states the main result consisting in the global existence of a weak solution to the system in Section 2, to be followed by several steps towards its proof. Thus, Section 5 introduces a sequence of non-degenerate approximations of the actual problem and Section 6 is concerned with deducing some a priori estimates to be used in Section 7 for the convergences necessary to prove the result announced in Section 4. Finally, in Section 8 we perform some numerical simulations in order to illustrate the model behavior and we also comment on the obtained results.

2 The model

Based on the models in [38, 44] we introduce here a PDE-ODE-ODE system characterizing the macroscopic dynamics of a tumor in interaction with the surrounding tissue in accordance with the go-or-grow dichotomy. The latter means that the tumor is assumed to be made up of two types of cells, which are either moving or mitotic and non-motile, whereby mutual transitions between the two phenotypes take place. Our model thus reads:

\begin{align}
\dot{c}_m &= -\alpha m + \beta vp + \nabla \cdot \left( \frac{\kappa_{m,vc}}{1 + vc} \nabla m - \frac{\kappa_{v,m}}{(1 + v)^2} \nabla v \right) \quad \text{in } \mathbb{R}^+ \times \Omega, \\
\dot{c}_p &= \alpha m - \beta vp + \mu_p (1 - c - \eta v) \quad \text{in } \mathbb{R}^+ \times \Omega, \\
\dot{c}_v &= \mu_v (1 - v) - \lambda v m \quad \text{in } \mathbb{R}^+ \times \Omega, \\
\frac{\kappa_{m,vc}}{1 + vc} \partial_\nu m - \frac{\kappa_{v,m}}{(1 + v)^2} \partial_\nu v &= 0 \quad \text{in } \mathbb{R}^+ \times \partial \Omega, \\
m(0) &= m_0, \quad p(0) = p_0, \quad v(0) = v_0 \quad \text{in } \Omega,
\end{align}

where $m$ and $p$ denote the densities of moving and proliferating cells, respectively, $v$ is the density of ECM fibers, all depending on time and position on a smooth bounded domain $\Omega \subset \mathbb{R}^N$. The positive constants $\alpha, \beta$ denote the transition rates between the two subpopulations, $\eta > 0$ is a constant scaling the concurrence with normal tissue in the proliferation process, $\kappa_{m,v}, \kappa_v$ are positive constants scaling the diffusion and the haptotactic sensitivity, $\lambda > 0$ is the decay rate of ECM due to interactions with (mesenchymally) motile cells, and $\mu_p, \mu_v$ are growth rates for the tumor cells and the tissue, respectively.
The total tumor burden is assessed by
\[ c(t, x) := m(t, x) + p(t, x). \]
Thus, system (2.1) includes a degenerate parabolic PDE for the moving and an ODE for the proliferating tumor cells, together with an ODE for the tissue density, supplemented by the initial and the ‘no-flux’ boundary conditions. The latter complies with the fact that cancer cells do not leave the tissue hosting the original tumor. As in [44], the diffusion coefficient in the equation for moving cells is nonlinear and can degenerate due to either tissue or tumor cell densities. The haptotaxis coefficient is nonlinear as well; its form is motivated by the microlocal cell-tissue interactions (as explained in [44]) and whence keeps a flavor of multiscale, also in a rather indirect fashion, as our system (2.1) is purely macroscopic. For explicit multiscale effects we refer to the related model in [38]. As observed there, the analysis done for a system involving a single population of cancer cells (hence without accounting for tumor heterogeneity in the sense mentioned above) does not directly carry over to a model discerning between moving and proliferating cells. One of the difficulties comes from the switching between the two populations, as the moving cells act on the one side as source for the proliferating ones, and on the other side as decay term for themselves and for the tissue. Another complicacy is due to the supplementary ODE for the proliferating cells, which -like the equation for tissue dynamics- lacks space derivatives, which was already a challenge in the more classical haptotaxis settings. Here the degenerate diffusion renders the problem even more complex.

3 Basic notation and functional spaces

We denote the Lebesgue measure of a set \( A \) by \( |A| \) and by \( \text{int} \ A \) its interior. 
Partial derivatives, in both classical and distributional sense, with respect to variables \( t \) and \( x_i \), will be denoted respectively by \( \partial_t \) and \( \partial_i \). Further, \( \nabla \), \( \nabla \cdot \) and \( \Delta \) stand for the spatial gradient, divergence and Laplace operators, respectively. \( \partial_i \) is the derivative with respect to the outward unit normal of \( \partial \Omega \).

We assume the reader to be familiar with the standard Lebesgue and Sobolev spaces and their usual properties, as well as with the more general \( L^p \) spaces of functions with values in general Banach spaces and with anisotropic Sobolev spaces. In particular, we need the Banach space
\[ W^{-1,1}(\Omega) := \left\{ u \in D'(\Omega) \mid u = u_0 + \sum_{k=1}^{N} \partial^k u_i \text{ for some } u_i \in L^1(\Omega), \ i = 0, \ldots, N \right\}, \]
\[ ||u||_{W^{-1,1}(\Omega)} := \inf \left\{ \sum_{k=0}^{N} ||u_k||_{1} \mid u = u_0 + \sum_{k=1}^{N} \partial^k u_i, \ u_i \in L^1(\Omega), \ i = 0, \ldots, N \right\}. \]

We will also make use of the Zygmund space [5, Chapter 6, Definition 6.1]
\[ L \log L(\Omega) := \left\{ u \in L^1(\Omega) \mid \int_{\Omega} M(u) \, dx < \infty \right\}, \text{ where } M(u) := \chi_{(|u|>1)}|u|\log|u|. \]

For \( p \in [1, \infty] \setminus \{2\} \), we write \( ||\cdot||_p \) in place of the \( \||\cdot||_{L^p(\Omega)} \)-norm. Throughout the paper, \( ||\cdot|| \) and \( (u,v) \) denote the standard \( L^2(\Omega) \)-norm and scalar product, respectively.
Finally, we make the following useful convention: For all indices \( i \), the quantity \( C_i \) denotes a non-negative constant or, alternatively, a non-negative function, which is non-decreasing in each of its arguments.

4 Problem setting and main result

In this section we propose a definition of weak solutions to system (2.1) and state our main result under the following assumptions:

**Assumptions 4.1 (Initial data).**
\begin{enumerate}
  \item \( m_0 \geq 0, \ m_0 \neq 0, \ m_0 \in L \log L(\Omega); \)
  \item \( p_0 \geq 0, \ p_0 \neq 0, \ p_0 \in L^{\infty}(\Omega); \)
  \item \( 0 \leq \nu_0 \leq 1, \ \nu_0 \neq 0, 1, \ \nu_0^\frac{1}{2} \in H^1(\Omega). \)
\end{enumerate}
The major challenge of model (2.1) lies in the fact that the diffusion coefficient in equation (2.1a) degenerates at \( v = 0 \). The latter seems to make it impossible to obtain an a priori estimate for the gradient of \( \varphi(m) \) in some Lebesgue space for any smooth, strictly increasing function \( \varphi \). As a workaround, we are forced to consider an auxiliary function which involves both \( m \) and \( v \) and whose gradient we are able to estimate.

This leads us to the following definition of weak solutions to (2.1):

**Definition 4.2 (Weak solution).** Let \( m_0, p_0, v_0 \) satisfy Assumptions 4.1. We call a triple of functions \( m, p : \mathbb{R}_0^+ \times \Omega \rightarrow \mathbb{R}_0^+ \), \( v : \mathbb{R}_0^+ \times \Omega \rightarrow [0, 1] \) a global weak solution of (2.1) if for all \( 0 < T < \infty \) it holds that

1. \( m \in L^\infty(0, T; L^1(\Omega)) \);
2. \( p \in L^\infty(0, T; L^\infty(\Omega)) \), \( \partial_t p \in L^1(0, T; L^1(\Omega)) \);
3. \( v^\frac{1}{2} \in L^\infty(0, T; H^1(\Omega)) \), \( \partial_t v \in L^1(0, T; L^1(\Omega)) \);
4. \( \nabla \left( v^\frac{1}{2}(m + 1)^\frac{1}{2} \left( \frac{\kappa_m c}{1 + v} + \frac{\kappa_v}{1 + v} \right) v^\frac{1}{2} (m + 1)^\frac{1}{2} \left( \nabla \left( v^\frac{1}{2}(m + 1)^\frac{1}{2} \right) - (m + 1)^\frac{1}{2} \nabla v^\frac{1}{2} \right) \right) \in L^1(0, T; L^1(\Omega)) \), \( \nabla \left( \frac{v^t}{\gamma + m} m \, d\tau \right) \in L^\infty(0, T; L^2(\Omega)) \);
5. \( (m, p, v) \) satisfies equation (2.1a) and the boundary condition (2.1d) in the following weak sense:

\[
\int_0^T \int_\Omega m_0 \varphi \, dx \psi(0) - \int_0^T \int_\Omega m \varphi \, dx \psi' \, dt = - \int_0^T \int_\Omega \left( \frac{\kappa_m c}{1 + v} + \frac{\kappa_v}{1 + v} \right) 2v^\frac{1}{2}(m + 1)^\frac{1}{2} \left( \nabla \left( v^\frac{1}{2}(m + 1)^\frac{1}{2} \right) - (m + 1)^\frac{1}{2} \nabla v^\frac{1}{2} \right) \cdot \nabla \varphi \psi \, dx \, dt + \kappa_v \nabla \left( \frac{v^t}{\gamma + m} m \, d\tau \right) \cdot \nabla \varphi \psi' + (-\alpha m + \beta vp) \varphi \psi \, dx \, dt \tag{4.1}
\]

for all \( \varphi \in W^{1,\infty}(\Omega) \) and \( \psi \in W^{1,\infty}(0, T) \) such that \( \psi(T) = 0 \);
6. \( (m, p, v) \) satisfies equations (2.1b)-(2.1c) in \( L^1(0, T; L^1(\Omega)) \);
7. \( p(0) = p_0 \), \( v(0) = v_0 \).

**Remark 4.3 (Weak formulation).** By using the chain and product rules and (where necessary) partial integration over \( \Omega \) and over \([0, T]\), it can be readily checked that (4.1) is, indeed, a weak reformulation of (2.1a) and (2.1d). Its somewhat nonstandard form is due to the fact that \( \nabla m \) in the diffusion term and the taxis flux term \( \frac{\kappa_m c}{1 + v} \nabla v \) might not exist even in \( L^1_{\text{loc}} \)-sense.

**Remark 4.4 (Initial conditions).** Since we are looking for solutions with

\[
p \in W^{1,1}(0, T; L^1(\Omega)),
\]

\[
v^\frac{1}{2} \in H^1(0, T; L^1(\Omega)),
\]

we have

\[
p \in C([0, T]; L^1(\Omega)),
\]

\[
v^\frac{1}{2} \in C([0, T]; L^1(\Omega)).
\]

Therefore, the initial conditions 7. in Definition 4.2 do make sense.

Our main result reads:

**Theorem 4.5 (Global existence).** Let \( \Omega \subset \mathbb{R}^N \), \( N \in \mathbb{N} \), be a smooth bounded domain and let \( \alpha, \beta, \eta, \kappa_m, \kappa_v, \lambda, \mu_p, \mu_v \) be positive constants. Then, for each triple of functions \( (m_0, p_0, v_0) \) satisfying Assumptions 4.1 there exists a global weak solution \( (m, p, v) \) (in terms of Definition 4.2) to the system (2.1).

The proof of Theorem 4.5 is based on a suitable approximation of the degenerate system (2.1) by a family of systems with nondegenerate diffusion of the migrating cells, derivation of a set of a priori estimates which ensure necessary compactness and, finally, the passage to the limit. While the overall structure of the proof is a standard one for a haptotaxis system, we encounter considerable difficulties in each of the three steps due to the previously mentioned degenerate diffusion in equation (2.1a), due to the ODEs (2.1b)-(2.1c) having no diffusion at all (i.e., everywhere degenerate), and, finally, due to the strong couplings.
5 Approximating problems

In this section we introduce a family of non-degenerate approximations for problem (2.1). For each relaxation parameter \( \varepsilon = (\varepsilon_1, \varepsilon_2, \varepsilon_3) \in (0,1)^3 \), the corresponding approximation reads

\[
\begin{align*}
\hat{\vartheta}_t m_\varepsilon &= -\alpha m_\varepsilon + \beta v_\varepsilon p_\varepsilon + \varepsilon_1 \Delta m_\varepsilon + \nabla \cdot \left( \frac{\kappa_m v_\varepsilon c_\varepsilon}{1 + v_\varepsilon c_\varepsilon} \nabla m_\varepsilon - \frac{\kappa_v m_\varepsilon}{(1 + v_\varepsilon)^2} \nabla v_\varepsilon \right) \quad \text{in } \mathbb{R}^+ \times \Omega, \\
\hat{\vartheta}_t p_\varepsilon &= \alpha m_\varepsilon - \beta v_\varepsilon p_\varepsilon + \mu p_\varepsilon (1 - c_\varepsilon - \eta v_\varepsilon) \quad \text{in } \mathbb{R}^+ \times \Omega, \\
\hat{\vartheta}_t v_\varepsilon &= \mu_v v_\varepsilon (1 - v_\varepsilon) - \lambda v_\varepsilon m_\varepsilon \quad \text{in } \mathbb{R}^+ \times \Omega, \\
\varepsilon_1 \hat{\vartheta}_t v_\varepsilon + \frac{\kappa_m v_\varepsilon c_\varepsilon}{1 + v_\varepsilon c_\varepsilon} \hat{\vartheta}_t m_\varepsilon - \frac{\kappa_v m_\varepsilon}{(1 + v_\varepsilon)^2} \hat{\vartheta}_t v_\varepsilon &= 0 \quad \text{in } \mathbb{R}^+ \times \partial \Omega, \\
m_\varepsilon(0) = m_{\varepsilon,0}, \quad p_\varepsilon(0) = p_{\varepsilon,0}, \quad v_\varepsilon(0) = v_{\varepsilon,0} \quad \text{in } \Omega,
\end{align*}
\]

where

\[ c_\varepsilon = m_\varepsilon + p_\varepsilon \]

and the families \( \{m_{\varepsilon,0}\}, \{p_{\varepsilon,0}\}\) and \( \{v_{\varepsilon,0}\}\) of sufficiently smooth and nonnegative initial values are parameterized by \( \varepsilon_2 \) and \( \varepsilon_3 \), respectively. They are yet to be specified below in Subsection 5.1.

For each \( \varepsilon \in (0,1)^3 \), system (5.1) has the form of a nondegenerate\(^1\) quasilinear haptotaxis system with respect to variables \( m_\varepsilon, p_\varepsilon, v_\varepsilon \). Thereby, the weak solutions can be defined similarly to Definition 4.2. In this case, 5. in Definition 4.2 is replaced by

5'. \( (m_\varepsilon, p_\varepsilon, v_\varepsilon) \) satisfies equation (5.1a) and the boundary condition (5.1d) in the following weak sense:

\[
\begin{align*}
\int_0^T \int_\Omega m_{\varepsilon,0} \varphi dx \psi(0) - \int_0^T \int_\Omega & m_\varepsilon \varphi dx \psi' dt \\
= & \int_0^T \int_\Omega -\varepsilon \nabla m_\varepsilon \cdot \nabla \varphi \psi dx dt \\
- & \int_0^T \int_\Omega \left( \frac{\kappa_m c_\varepsilon}{1 + v_\varepsilon c_\varepsilon} + \frac{\kappa_v}{1 + v_\varepsilon} \right) 2v_\varepsilon^{\frac{3}{2}} (m_\varepsilon + 1)^{\frac{3}{2}} \left( \nabla \left( v_\varepsilon^{\frac{3}{2}} (m_\varepsilon + 1)^{\frac{1}{2}} \right) - (m_\varepsilon + 1)^{\frac{3}{2}} \nabla v_\varepsilon \right) \cdot \nabla \varphi \psi \\
+ & \kappa_v \nabla \left( \int_0^t \frac{v_\varepsilon}{1 + v_\varepsilon} m_\varepsilon d\tau \right) \cdot \nabla \varphi \psi + (-\alpha m_\varepsilon + \beta v_\varepsilon p_\varepsilon) \varphi \psi dx dt
\end{align*}
\]

for all \( \varphi \in W^{1,\infty}(\Omega) \) and \( \psi \in W^{1,\infty}(0,T) \) such that \( \psi(T) = 0 \).

The global existence of nonnegative weak solutions for system (5.1) can be obtained in a standard way. We refer the reader to our proof in [44] where we dealt with a similar situation. It is based on further regularizations, Amann’s theory for abstract parabolic quasilinear systems [1], and a priori estimates. We omit those details here.

It is clear that for \( \varepsilon = 0 \) we regain - at least formally - the original degenerate haptotaxis system (2.1). As it turns out (see the subsequent Section 7), a weak solution to (2.1) can be obtained as a limit of a sequence of solutions to (5.1).

In order to shorten the writing, we will sometimes use the following notation for the flux and reaction terms, respectively:

\[
\begin{align*}
q_\varepsilon := & \varepsilon_1 \nabla m_\varepsilon + \frac{\kappa_m v_\varepsilon c_\varepsilon}{1 + v_\varepsilon c_\varepsilon} \nabla m_\varepsilon - \frac{\kappa_v m_\varepsilon}{(1 + v_\varepsilon)^2} \nabla v_\varepsilon, \\
f_\varepsilon := & -\alpha m_\varepsilon + \beta v_\varepsilon p_\varepsilon
\end{align*}
\]

\(^1\)in the sense that the parabolic PDE for the moving cells is nondegenerate.
5.1 Approximating initial data

Our next step is to construct a suitable family of approximations to the initial data. Since we assume that \((m_0, p_0, v_0)\) satisfies Assumptions 4.1, there exists for each \((\varepsilon_2, \varepsilon_3) \in (0, 1)^2\) an approximation triple \((m_{\varepsilon_0}, p_{\varepsilon_0}, v_{\varepsilon_0})\) with the following properties:

\[
\begin{align*}
& m_{\varepsilon_0}, p_{\varepsilon_0}, v_{\varepsilon_0}^\frac{1}{2} \in W^{1,\infty}(\Omega), \\
& m_{\varepsilon_0}, p_{\varepsilon_0} \geq 0, \ 0 \leq v_{\varepsilon_0} \leq 1 \text{ in } \Omega, \ m_{\varepsilon_0}, p_{\varepsilon_0}, v_{\varepsilon_0} \neq 0, \\
& \|M(m_{\varepsilon_0})\|_1 \leq 2 \|M(m_0)\|_1, \\
& \|\nabla v_{\varepsilon_0}^\frac{1}{2}\| \leq 2 \|v_0^\frac{1}{2}\|_{H^1(\Omega)}, \\
& \|m_{\varepsilon_0} - m_0\|_1 \leq \varepsilon_2, \\
& \|p_{\varepsilon_0} - p_0\|_{\infty} \leq \varepsilon_2, \\
& \|v_{\varepsilon_0}^\frac{1}{2} - v_0^\frac{1}{2}\| \leq \varepsilon_3.
\end{align*}
\]

(5.5) (5.6) (5.7) (5.8) (5.9) (5.10) (5.11)

Recall that our aim is to pass to the limit for \(\varepsilon \to 0\) in the approximating problem. Since equation (5.1c) is an ODE, the set \(\{v(t, \cdot) = 0\}\) is preserved in time (possibly up to some subsets of measure zero). Therefore, it turns out that we have to pay particular care at the set \(\{v_{\varepsilon_0} = 0\}\) whose interior should not shrink substantially with respect to \(\{v_0 = 0\}\). Following the idea from [44], we assume that

\[
\{|v_0 = 0\} \cup \{v_{\varepsilon_0} = 0\} \leq \varepsilon_3.
\]

(5.12)

Indeed, to justify (5.11) we recall here our argument from [44] for the convenience of the reader. Due to a Lusin property for Sobolev functions [12, Chapter 6, Theorem 6.14], there exists a function \(\xi\) such that

\[
\xi \in W^{1,\infty}(\Omega), \\
\|\xi\|_{H^1(\Omega)} \leq 2 \|v_0^\frac{1}{2}\|_{H^1(\Omega)}, \\
\left\{\xi \neq v_0^\frac{1}{2}\right\} \leq \frac{\varepsilon_3}{4}.
\]

(5.13) (5.14) (5.15)

We define

\[
v_{\varepsilon_0} := \left(\min\{\xi, 1\} - \frac{\varepsilon_3}{2|\Omega|}\right)^2.
\]

Let us check that \(v_{\varepsilon_0}\) satisfies the above assumptions. Indeed, due to (5.13)-(5.14), we have that

\[
v_{\varepsilon_0}^\frac{1}{2} \in W^{1,\infty}(\Omega), \\
\left\|\nabla v_{\varepsilon_0}^\frac{1}{2}\right\| \leq \|\nabla \xi\| \leq 2 \|v_0^\frac{1}{2}\|_{H^1(\Omega)},
\]

and

\[
\left\|v_{\varepsilon_0}^\frac{1}{2} - v_0^\frac{1}{2}\right\| \leq 2 \left\{\xi \neq v_0^\frac{1}{2}\right\} + \left\|\chi_{\{\xi = v_0^\frac{1}{2}\}} \left(\left(\xi - \frac{\varepsilon_3}{2|\Omega|}\right)_{\varepsilon_3} - \xi\right)\right\|_{H^1(\Omega)}
\]

\leq \varepsilon_3.
\]

Moreover, it holds that

\[
\{\xi = 0\} \subset \left\{\min\{\xi, 1\} < \frac{\varepsilon_3}{2|\Omega|}\right\} \subset \left\{\min\{\xi, 1\} \leq \frac{\varepsilon_3}{2|\Omega|}\right\} \cup \partial \Omega = \text{int} \{v_{\varepsilon_0} = 0\} \cup \partial \Omega.
\]

(5.16)

Combining (5.15) and (5.16), we obtain (5.12).

6 A priori estimates

In this section we establish, based on system (5.1), several uniform a priori estimates for the functions \(m_\varepsilon, p_\varepsilon, v_\varepsilon\) and their combinations, which we will use in the existence proof (see Section 7 below). Our calculations make use of the regularity which the solutions of (5.1) do have. While operating with the weak derivatives, we use the weak chain and product rules. Another way to justify the calculation is via further approximations, as was done in [44].
Uniform boundedness of \( v_\varepsilon \)

Since the ODE (5.1c) has the form
\[
\partial_t v_\varepsilon = f_\varepsilon(v_\varepsilon, m_\varepsilon)
\]
with \( f_\varepsilon(0, m) = 0, f_\varepsilon(1, m) \leq 0 \) for all \( m \geq 0 \), and the initial value satisfies \( 0 \leq v_{\varepsilon, 0} \leq 1 \) (compare (5.6)), we obtain using standard ODE theory that
\[
0 \leq v_\varepsilon \leq 1 \text{ in } (0, T) \times \Omega.
\]
holds a priori. Below we will use this simple estimate without referring to it explicitly.

Uniform boundedness of \( p_\varepsilon \)

Equation (5.1b) for \( p_\varepsilon \) can be rewritten in the following way:
\[
\partial_t p_\varepsilon = -(\mu_P p_\varepsilon - \alpha) m_\varepsilon - (\beta + \mu_P \eta) v_\varepsilon p_\varepsilon + \mu_P (1 - p_\varepsilon).
\]
(6.1)

Since \( m_\varepsilon, v_\varepsilon \geq 0 \), one readily obtains from (6.1) using the Gronwall lemma that
\[
p_\varepsilon \leq C_p.
\]
(6.2)

Energy-type estimates

We now turn to equation (5.1c) for \( v_\varepsilon \). On both sides of (5.1c), we divide by \( \varepsilon^2 (1 + v_\varepsilon) \) and then apply the gradient operator. Thus we obtain that
\[
\partial_t \nabla \int_0^{v_\varepsilon} \frac{1}{s^{\frac{3}{2}}(1 + s)} \, ds = -\lambda \frac{v_\varepsilon^2}{1 + v_\varepsilon} \nabla m_\varepsilon - \frac{\lambda (1 - v_\varepsilon) m_\varepsilon + \mu_V (-1 + 4 v_\varepsilon + v_\varepsilon^2)}{(1 + v_\varepsilon)^2} \nabla v_\varepsilon^2.
\]
(6.3)

Further, we multiply (5.1a) by \( \ln m_\varepsilon \) and (6.3) by \( \nabla \int_0^{v_\varepsilon} \frac{1}{s^{\frac{3}{2}}(1 + s)} \, ds \) and integrate over \( \Omega \) using partial integration and the boundary conditions where necessary. Adding the resulting identities together, we obtain after some calculation that
\[
\begin{align*}
\frac{d}{dt} \left( 1 + m_\varepsilon \ln m_\varepsilon - m_\varepsilon \right) + \frac{2\kappa_V}{\lambda} \left( \frac{1}{1 + v_\varepsilon^2} \left| \nabla v_\varepsilon^2 \right|^2 \right) + \varepsilon_1 \left\| \nabla m_\varepsilon^2 \right\|^2 + 4 \left( \frac{\kappa \varepsilon \mu_V c_\varepsilon}{1 + v_\varepsilon c_\varepsilon} \right) \left| \nabla m_\varepsilon^2 \right|^2 \right) \\
+ \frac{2\kappa_V}{\lambda} \left( \lambda (1 - v_\varepsilon) m_\varepsilon + 5\mu_V c_\varepsilon + \mu_V c_\varepsilon^2 \right) \left| \nabla v_\varepsilon^2 \right|^2 + \alpha(m_\varepsilon, \ln m_\varepsilon) \\
\leq \beta(v_\varepsilon p_\varepsilon, \ln m_\varepsilon) + \frac{2\mu_V \kappa_V}{\lambda} \left( \frac{1}{1 + v_\varepsilon^2} \right) \left| \nabla v_\varepsilon^2 \right|^2
\end{align*}
\]

By using the Gronwall lemma and (6.2), we thus arrive, for arbitrary \( T \in \mathbb{R}^+ \), at the estimates
\[
\begin{align*}
\sup_{t \in [0, T]} (\chi(m_\varepsilon > 1), m_\varepsilon \ln m_\varepsilon) & \leq C_1(T), \quad (6.4) \\
\sup_{t \in [0, T]} \left\| \nabla v_\varepsilon^2 \right\|^2 & \leq C_1(T), \quad (6.5) \\
\int_0^T \left( \frac{v_\varepsilon c_\varepsilon}{1 + v_\varepsilon c_\varepsilon} \left| \nabla m_\varepsilon^2 \right|^2 \right) \, dt & \leq C_1(T), \quad (6.6) \\
\int_0^T (1 - v_\varepsilon) m_\varepsilon \left| \nabla v_\varepsilon^2 \right|^2 \, dt & \leq C_1(T), \quad (6.7) \\
\int_0^T (v_\varepsilon p_\varepsilon - \chi(m_\varepsilon < 1) \ln m_\varepsilon) \, dt & \leq C_1(T) \quad (6.8) \\
\int_0^T \left| \nabla m_\varepsilon^2 \right|^2 \, dt & \leq \varepsilon_1^{-1} C_1(T). \quad (6.9)
\end{align*}
\]
Since \( s \mapsto \frac{s}{1+s} \) is a monotonically increasing function, (6.6) yields that

\[
\int_0^T \left( \frac{v_c}{1 + v_c m_c}, \left| \nabla m_c \right|^2 \right) dt = 4 \int_0^T \left( \frac{v_c m_c}{1 + v_c m_c}, \left| \nabla m_c \right|^2 \right) dt \\
\leq 4 \int_0^T \left( \frac{v_c}{1 + v_c m_c}, \left| \nabla m_c \right|^2 \right) dt \\
\leq C_2(T).
\]  

(6.10)

Consequently, we also have that

\[
\int_0^T \left( v_c, \left| \nabla (1 + m_c)^\frac{1}{2} \right|^2 \right) dt = \frac{1}{4} \int_0^T \left( \frac{v_c}{1 + m_c}, \left| \nabla m_c \right|^2 \right) dt \\
\leq \frac{1}{4} \int_0^T \left( \frac{v_c}{1 + v_c m_c}, \left| \nabla m_c \right|^2 \right) dt \\
\leq C_3(T).
\]  

(6.11)

**Uniform integrability of \( m_c \)**

It follows with (6.4) that

\[
\| m_c \|_{L^\infty(0,T;L^1(\Omega))} \leq C_4(T).
\]  

(6.12)

Moreover, due to the de la Vallée-Poussin theorem, we conclude with (6.4) that \( \{ m_c \} \) is uniformly integrable in \((0,T) \times \Omega\).

(6.13)

**Uniform integrability of \( \nabla \left( v_c^\frac{1}{2} (m_c + 1)^\frac{1}{2} \right) \)**

Due to (6.13), it holds that

\[
\left\{ v_c^\frac{1}{2} (m_c + 1)^\frac{1}{2} \right\} \text{ is uniformly integrable in } (0,T) \times \Omega.
\]  

(6.14)

We compute that

\[
\nabla \left( v_c^\frac{1}{2} (m_c + 1)^\frac{1}{2} \right) = v_c^\frac{1}{2} \nabla (m_c + 1)^\frac{1}{2} + (m_c + 1)^\frac{1}{2} \nabla v_c^\frac{1}{2}.
\]  

(6.15)

Combining (6.5), (6.11), (6.13), (6.15) and using the de la Vallée-Poussin theorem and Lemma A.1, we conclude that

\[
\left\{ \nabla \left( v_c^\frac{1}{2} (m_c + 1)^\frac{1}{2} \right) \right\} \text{ is uniformly integrable in } (0,T) \times \Omega.
\]  

(6.16)

**Uniform integrability of the reaction term in (5.1a)**

It immediately follows with (6.2), (6.12), (6.13) that

\[
\{ f_c \} \text{ is uniformly integrable in } (0,T) \times \Omega
\]  

(6.17)

and

\[
\| f_c \|_{L^\infty(0,T;L^1(\Omega))} \leq C_5(T).
\]  

(6.18)

**Uniform integrability of the diffusion flux in (5.1a)**

We first deal with the relaxation term. We have that

\[
\varepsilon^\frac{1}{2} \left| \nabla m_c \right| = 2\varepsilon^\frac{1}{2} \left| \nabla m_c \right| m_c^\frac{1}{2}.
\]  

(6.19)

Using the Hölder inequality, we obtain with (6.9), (6.12) and (6.19) that

\[
\varepsilon^1 \| \nabla m_c \|_{L^1(0,T;L^1(\Omega))} \leq \varepsilon^\frac{1}{2} C_6(T).
\]  

(6.20)
For the degenerate part of the diffusion flux, we have that
\[ \frac{-v_\varepsilon c_\varepsilon |\nabla m_\varepsilon|}{1 + v_\varepsilon c_\varepsilon} = 2 \left( \frac{-v_\varepsilon c_\varepsilon}{1 + v_\varepsilon c_\varepsilon} \right) \frac{1}{2} m_\varepsilon \left( \frac{-v_\varepsilon c_\varepsilon}{1 + v_\varepsilon c_\varepsilon} |\nabla m_\varepsilon| \right)^{\frac{1}{2}}. \] (6.21)

Combining (6.6) and (6.13), we obtain with Lemma A.1 that
\[ \left\{ \frac{v_\varepsilon c_\varepsilon |\nabla m_\varepsilon|}{1 + v_\varepsilon c_\varepsilon} \right\} \text{ is uniformly integrable in } (0, T) \times \Omega, \] (6.22)
so that
\[ \left\| \frac{v_\varepsilon c_\varepsilon |\nabla m_\varepsilon|}{1 + v_\varepsilon c_\varepsilon} \right\|_{L^1(0, T; L^1(\Omega))} \leq C_7(T). \] (6.23)

**Uniform integrability of the taxis flux in (5.1a)**

Let us next consider the taxis part of the flux. We compute that
\[ \frac{m_\varepsilon}{(1 + v_\varepsilon)^2} \nabla v_\varepsilon = m_\varepsilon \nabla \left( \frac{v_\varepsilon}{1 + v_\varepsilon} \right) = \nabla \left( \frac{v_\varepsilon m_\varepsilon}{1 + v_\varepsilon} \right) - \frac{v_\varepsilon}{1 + v_\varepsilon} \nabla m_\varepsilon. \] (6.24)

For the second summand on the right-hand side of (6.24), we have that
\[ \frac{v_\varepsilon}{1 + v_\varepsilon} \nabla m_\varepsilon = 2 \frac{v_\varepsilon^\frac{1}{2}}{1 + v_\varepsilon} (m_\varepsilon + 1)^\frac{3}{2} v_\varepsilon^\frac{1}{2} \nabla (m_\varepsilon + 1)^\frac{1}{2} \] (6.25)

We use (6.11), (6.13) and Lemma A.1 in order to conclude from (6.25) that
\[ \left\{ \frac{v_\varepsilon}{1 + v_\varepsilon} \nabla m_\varepsilon \right\} \text{ is uniformly integrable in } (0, T) \times \Omega. \] (6.26)

As for the first summand on the right-hand side of (6.24), we seek for an estimate for its integral over \( (0, t) \) (compare Definition 4.2). On both sides of equation (5.1c), we divide by \( 1 + v_\varepsilon \), apply the space gradient and finally integrate over \( (0, t) \). This yields that
\[ \frac{1}{1 + v_\varepsilon} \nabla v_\varepsilon(t) - \frac{1}{1 + v_\varepsilon(0)} \nabla v_\varepsilon(0) = \mu_v \int_0^t \left( \frac{s(1-s)}{1+s} \right) |s=v_\varepsilon(\tau) \nabla v_\varepsilon(\tau) - \lambda \nabla \left( \int_0^\tau \frac{v_\varepsilon m_\varepsilon}{1 + v_\varepsilon} d\tau \right). \] (6.27)

Since \( s \mapsto \frac{s(1-s)}{1+s} \) is continuously differentiable, we conclude from (6.27) using (6.5) that
\[ \left\| \nabla \left( \int_0^t \frac{v_\varepsilon m_\varepsilon}{1 + v_\varepsilon} d\tau \right) \right\|_{L^\infty((0, T; L^2(\Omega)))} \leq C_8(T). \] (6.28)

**Estimates involving \( \partial_t v_\varepsilon \)**

We divide equation (5.1c) by \( v_\varepsilon \):
\[ \frac{1}{v_\varepsilon} \partial_t v_\varepsilon = \mu_v (1 - v_\varepsilon) - \lambda m_\varepsilon. \] (6.29)

Together with (6.12), (6.29) yields that
\[ \left\| \frac{1}{v_\varepsilon} \partial_t v_\varepsilon \right\|_{L^\infty((0, T; L^1(\Omega)))} \leq C_9(T), \] (6.30)
so that, consequently,
\[ \left\| \partial_t v_\varepsilon^\frac{1}{2} \right\|_{L^\infty((0, T; L^1(\Omega)))} \leq C_{10}(T). \] (6.31)
Estimates for \( \ln(1 + v_{\varepsilon}^1 m_{\varepsilon}) \)

Above we obtained uniform (in \( \varepsilon \)) estimates for both time and spacial derivatives of \( v_{\varepsilon} \). Owing to the fact that the original diffusion coefficient in (2.1a) is degenerate in \( v \), it does not seem possible to obtain similar estimates for \( m_{\varepsilon} \) or, at least, for \( \varphi(m_{\varepsilon}) \) for a smooth, strictly increasing, and independent of \( \varepsilon \) function \( \varphi \). In order to overcome this difficulty and gain some information on \( m_{\varepsilon} \) in the set \( \{ v_{\varepsilon} > 0 \} \), we introduce for \( \varepsilon \in (0, 1) \) an auxiliary function which involves both \( m_{\varepsilon} \) and \( v_{\varepsilon} \):

\[
    u_{\varepsilon} := \ln \left( 1 + v_{\varepsilon}^1 m_{\varepsilon} \right). \tag{6.32}
\]

Since

\[
    0 \leq \ln \left( 1 + v_{\varepsilon}^2 m_{\varepsilon} \right) \leq m_{\varepsilon},
\]

we obtain with (6.13) that

\[
    \{ u_{\varepsilon} \} \text{ is uniformly integrable in } (0, T) \times \Omega.
\]

As it turns out, the family \( \{ u_{\varepsilon} \} \) is (strongly) precompact in \( L^1(0, T; L^1(\Omega)) \). To prove this, we need uniform estimates for the partial derivatives of \( u_{\varepsilon} \) in some parabolic Sobolev spaces.

We first study the spatial gradient of \( u_{\varepsilon} \). We compute that

\[
    \nabla u_{\varepsilon} = \frac{m_{\varepsilon}}{1 + v_{\varepsilon}^2 m_{\varepsilon}} \nabla v_{\varepsilon}^1 + \frac{v_{\varepsilon}^1}{1 + v_{\varepsilon}^2 m_{\varepsilon}} \nabla m_{\varepsilon}. \tag{6.33}
\]

Using the trivial inequality

\[
    1 \leq v_{\varepsilon}^4 + (1 - v_{\varepsilon})^2, \tag{6.34}
\]

we estimate the first summand on the right-hand side of (6.33) in the following way:

\[
    \frac{m_{\varepsilon} \left| \nabla v_{\varepsilon}^1 \right|}{1 + v_{\varepsilon}^2 m_{\varepsilon}} \leq \frac{v_{\varepsilon}^1}{1 + v_{\varepsilon}^2 m_{\varepsilon}} \frac{m_{\varepsilon} \left| \nabla v_{\varepsilon}^1 \right|}{1 + v_{\varepsilon}^2 m_{\varepsilon}} + \frac{(1 - v_{\varepsilon})^2}{2} \frac{m_{\varepsilon} \left| \nabla v_{\varepsilon}^1 \right|}{1 + v_{\varepsilon}^2 m_{\varepsilon}} \\
    \leq \left| \nabla v_{\varepsilon}^1 \right| + \frac{1}{2} m_{\varepsilon} \left| \nabla v_{\varepsilon}^1 \right|^2. \tag{6.35}
\]

Using estimates (6.5), (6.7), (6.12), we conclude from (6.35) that

\[
    \left\| \frac{m_{\varepsilon} \left| \nabla v_{\varepsilon}^1 \right|}{1 + v_{\varepsilon}^2 m_{\varepsilon}} \right\|_{L^1(0, T; L^1(\Omega))} \leq C_{11}(T). \tag{6.36}
\]

For the second summand on the right-hand side of (6.33), we have that

\[
    \frac{v_{\varepsilon}^1 \left| \nabla m_{\varepsilon} \right|}{1 + v_{\varepsilon}^2 m_{\varepsilon}} \leq \frac{v_{\varepsilon}^1 \left| \nabla m_{\varepsilon} \right|}{1 + v_{\varepsilon}^2 m_{\varepsilon}} \leq \frac{v_{\varepsilon}^1 \left| \nabla m_{\varepsilon} \right|}{(1 + v_{\varepsilon} m_{\varepsilon})^2}. \tag{6.37}
\]

Due to (6.10), (6.37) yields that

\[
    \left\| \frac{v_{\varepsilon}^1 \left| \nabla m_{\varepsilon} \right|}{1 + v_{\varepsilon}^2 m_{\varepsilon}} \left. \right\|_{L^2((0, T) \times \Omega)} \leq C_{12}(T). \tag{6.38}
\]

Altogether, we obtain from (6.33) with (6.36), (6.38) that

\[
    \left\| \nabla u_{\varepsilon} \right\|_{L^1(0, T; L^1(\Omega))} \leq C_{13}(T). \tag{6.39}
\]
Next, we deal with the time derivative of $u_\varepsilon$. We compute that
\[
\partial_t u_\varepsilon = \frac{1}{2} \frac{v_\varepsilon^2 m_\varepsilon}{1 + v_\varepsilon^2 m_\varepsilon} \varepsilon \partial_t v_\varepsilon + \frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} \partial_t m_\varepsilon. \tag{6.40}
\]

We estimate the first summand on the right-hand side of (6.40) as follows:
\[
\frac{1}{2} \left| \frac{v_\varepsilon^2 m_\varepsilon}{1 + v_\varepsilon^2 m_\varepsilon} \varepsilon \partial_t v_\varepsilon \right| \leq \frac{1}{2} \left| \frac{v_\varepsilon}{v_\varepsilon} \partial_t v_\varepsilon \right|. \tag{6.41}
\]

Combining (6.30) and (6.41), we obtain that
\[
\frac{1}{2} \left\| \frac{v_\varepsilon^2 m_\varepsilon}{1 + v_\varepsilon^2 m_\varepsilon} \varepsilon \partial_t v_\varepsilon \right\|_{L^\infty(0,T; L^1(\Omega))} \leq C_{14}. \tag{6.42}
\]

In order to estimate the second summand on the right-hand side of (6.40), we multiply both sides of equation (5.1a) by $\frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon}$ and obtain (compare the notation in (5.3)-(5.4)) that
\[
\frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} \varepsilon \partial_t m_\varepsilon = \nabla \cdot \left( \frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} q_\varepsilon \right) - q_\varepsilon \cdot \nabla \frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} + \frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} f_\varepsilon. \tag{6.43}
\]

Since
\[
\frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} \leq 1,
\]

it holds that
\[
\frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} |f_\varepsilon| \leq |f_\varepsilon|.
\]

Hence, we conclude with (6.18) that
\[
\left\| \frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} f_\varepsilon \right\|_{L^\infty(0,T; L^1(\Omega))} \leq C_{15}(T). \tag{6.44}
\]

For the term inside the divergence operator in (6.43), we have that
\[
\frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} q_\varepsilon \leq \frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} \left( \varepsilon_1 |\nabla m_\varepsilon| + \kappa_m \frac{v_\varepsilon c_\varepsilon |\nabla m_\varepsilon|}{1 + v_\varepsilon c_\varepsilon} + \kappa_v \frac{2 v_\varepsilon^2 m_\varepsilon |\nabla v_\varepsilon^2|}{(1 + v_\varepsilon)^2} \right)
\]
\[
\leq \varepsilon_1 |\nabla m_\varepsilon| + \kappa_m \frac{v_\varepsilon c_\varepsilon |\nabla m_\varepsilon|}{1 + v_\varepsilon c_\varepsilon} + 2 \kappa_v |\nabla v_\varepsilon^2|. \tag{6.45}
\]

Using (6.5), (6.20), (6.23), we obtain from (6.45) that
\[
\left\| \frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} q_\varepsilon \right\|_{L^1(0,T; L^1(\Omega))} \leq C_{16}(T). \tag{6.46}
\]

It remains to estimate the second term on the right-hand side of (6.43). We compute that
\[
\nabla \frac{v_\varepsilon}{1 + v_\varepsilon^2 m_\varepsilon} = -\frac{v_\varepsilon}{(1 + v_\varepsilon^2 m_\varepsilon)^2} \nabla m_\varepsilon + \frac{1}{(1 + v_\varepsilon^2 m_\varepsilon)^2} \nabla v_\varepsilon^2,
\]
so that
\[
\left| q_\varepsilon \cdot \nabla \frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} \right| \leq |q_\varepsilon| \left| \nabla \frac{v_\varepsilon^2}{1 + v_\varepsilon^2 m_\varepsilon} \right|.
\]
Using (6.34) and (6.2) where necessary, we get the following estimates:

\[
\begin{align*}
\varepsilon_{1} |\nabla m_{e}| & \leq \frac{v_{e} |\nabla m_{e}|}{(1 + \frac{1}{2} v_{e} m_{e})^2} \leq \frac{v_{e} |\nabla m_{e}|^2}{1 + v_{e} m_{e}}, \\
\frac{v_{e} c_{e} |\nabla m_{e}|}{1 + v_{e} c_{e}} & \leq \frac{v_{e} |\nabla m_{e}|^2}{1 + v_{e} m_{e}} \\
\frac{v_{e} \frac{1}{2} m_{e} |\nabla v_{e}^2| - v_{e} |\nabla m_{e}|}{(1 + \frac{1}{2} v_{e} m_{e})^2} & \leq \frac{v_{e} |\nabla m_{e}|^2}{1 + v_{e} m_{e}} \frac{1}{2} |\nabla v_{e}^2| \\
& \leq \frac{v_{e} |\nabla m_{e}|^2}{2 (1 + v_{e} m_{e})} + \frac{1}{2} |\nabla v_{e}^2|^2, \\
\frac{|\nabla m_{e}| |\nabla v_{e}^2|}{(1 + \frac{1}{2} v_{e} m_{e})^2} & \leq \frac{v_{e} \frac{1}{2} m_{e} |\nabla v_{e}^2|}{(1 + \frac{1}{2} v_{e} m_{e})^2} + \left(1 - v_{e} \frac{1}{2} m_{e} |\nabla m_{e}| \frac{|\nabla v_{e}^2|}{(1 + \frac{1}{2} v_{e} m_{e})^2} \right) \\
& \leq \frac{v_{e} |\nabla m_{e}|^2}{2 (1 + v_{e} m_{e})} + \frac{1}{2} |\nabla v_{e}^2|^2 + \frac{|\nabla m_{e}|^2}{2} + (1 - v_{e} \frac{1}{2} m_{e} |\nabla v_{e}^2|^2), \\
\frac{v_{e} c_{e} |\nabla m_{e}| |\nabla v_{e}^2|}{1 + v_{e} c_{e}} & \leq \frac{2 v_{e} \frac{1}{2} m_{e} (m_{e} + p_{e}) \frac{1}{2}}{(1 + \frac{1}{2} v_{e} m_{e})^2} \frac{v_{e} c_{e} |\nabla m_{e}|^2}{1 + v_{e} c_{e}} |\nabla v_{e}^2| \\
& \leq \frac{2 v_{e} \frac{1}{2} m_{e} + 2C_{p} (v_{e} m_{e}) \frac{1}{2}}{(1 + \frac{1}{2} v_{e} m_{e})^2} \frac{v_{e} c_{e} |\nabla m_{e}|^2}{1 + v_{e} c_{e}} |\nabla v_{e}^2| \\
& \leq C_{18} \frac{v_{e} c_{e} |\nabla m_{e}|^2}{1 + v_{e} c_{e}} + C_{18} |\nabla v_{e}^2|, \\
v_{e} \frac{1}{2} m_{e} |\nabla v_{e}^2| & \leq \frac{|\nabla v_{e}^2|}{(1 + \frac{1}{2} v_{e} m_{e})^2} \leq |\nabla v_{e}^2|^2.
\end{align*}
\]

Combining (6.47)-(6.53) with (6.5)-(6.7), (6.9), (6.10), (6.12), we obtain that

\[
\left| q_{e} \cdot \nabla \frac{v_{e}^2}{1 + v_{e} \frac{1}{2} m_{e}} \right|_{L^{1}(0, T; L^{1}(\Omega))} \leq C_{19}(T).
\]
Therefore, (6.43) together with (6.44), (6.46) and (6.54) yield that

\[
\left\| \varepsilon_{\gamma} \frac{\partial_{\gamma} m_{\varepsilon}}{1 + \varepsilon_{\gamma} m_{\varepsilon}} \right\|_{L^1(0,T;W^{-1,1}(\Omega))} \leq C_{20}(T). \tag{6.55}
\]

Finally, with the help of estimates (6.42) and (6.55), we obtain from (6.40) that

\[
\left\| \partial_{t} u_{\varepsilon} \right\|_{L^1(0,T;W^{-1,1}(\Omega))} \leq C_{21}(T). \tag{6.56}
\]

**Estimates for** \( m_{\varepsilon} \) **in** \((0,T) \times \text{int}\{v_{\varepsilon,0} = 0\} **While studying the function** \( m_{\varepsilon} \), the auxiliary function \( u_{\varepsilon} \) introduced in (6.32) is of use only in the set \( \{v_{\varepsilon} > 0\} \). It clearly reveals no further information about the behaviour of \( m_{\varepsilon} \) over the level sets \( \{v_{\varepsilon}(t) = 0\}, t \in (0,T) \), each of whom almost coincide with \( \{v_{\varepsilon,0} = 0\} \). The latter is to mean that \( \{v_{\varepsilon}(t) = 0\} \) differs from \( \{v_{\varepsilon,0} = 0\} \) by a null set and is thus preserved in time. In order to see this, let us divide both sides of the ODE (5.1c) by \( v_{\varepsilon} \) and integrate over \((0,t)\) for arbitrary \( t \in (0,T) \). We obtain that

\[
\ln(v_{\varepsilon}(t)) - \ln(v_{\varepsilon,0}) = \int_{0}^{t} \mu_{\varepsilon}(1 - v_{\varepsilon}) \, dt - \lambda \int_{0}^{t} m_{\varepsilon} \, dt. \tag{6.57}
\]

Since \( 0 \leq v_{\varepsilon} \leq 1 \) and \( m_{\varepsilon} \in L^1(0,T;L^1(\Omega)) \), the right-hand side of (6.57) is finite a.e. in \( \Omega \). Hence, the same holds for the left-hand side of (6.57). But this means that for all \( t \in \mathbb{R}^+ \) it necessarily holds that

\[
v_{\varepsilon}(t) > 0 \text{ a.e. in } \{v_{\varepsilon,0} > 0\}, \tag{6.58a}
\]

\[
v_{\varepsilon}(t) = 0 \text{ a.e. in } \{v_{\varepsilon,0} = 0\}. \tag{6.58b}
\]

Similarly, we obtain from the original equation (2.1c) that

\[
v(t) > 0 \text{ a.e. in } \{v_0 > 0\}, \tag{6.59a}
\]

\[
v(t) = 0 \text{ a.e. in } \{v_0 = 0\}. \tag{6.59b}
\]

Observe that, at least in \((0,T) \times \text{int}\{v_{\varepsilon,0} = 0\}, m_{\varepsilon} \) solves the linear initial value problem

\[
\partial_{t} m_{\varepsilon} = \varepsilon_{1} \Delta m_{\varepsilon} - \alpha m_{\varepsilon} \text{ in } \mathbb{R}^+ \times \text{int}\{v_{\varepsilon,0} = 0\}, \tag{6.60a}
\]

\[
m_{\varepsilon}(0) = m_{\varepsilon,0} \text{ in } \text{int}\{v_{\varepsilon,0} = 0\}. \tag{6.60b}
\]

Combining (6.12) and (6.20), we conclude from (6.60a) that

\[
\|\partial_{t} m_{\varepsilon}\|_{L^1(0,T;W^{-1,1}(\text{int}\{v_{\varepsilon,0} = 0\}))} \leq C_{22}(T). \tag{6.61}
\]

Since \( m_{\varepsilon,0} \) is smooth, \( m_{\varepsilon} \) is a classical solution to (6.60a). Differentiating (6.60a) with respect to \( x_i, i \in \{1, \ldots, N\} \), we obtain that

\[
\partial_{i} \partial_{x_i} m_{\varepsilon} = \varepsilon_{1} \Delta \partial_{x_i} m_{\varepsilon} - \alpha \partial_{x_i} m_{\varepsilon}. \tag{6.62}
\]

Let now \( \varphi \) be some smooth cut-off function with \( \text{supp} \varphi \subset \text{int}\{v_{\varepsilon,0} = 0\} \) and let \( a \in (1,2) \), the latter to be specified below. Multiplying (6.62) by \( a\varphi^2|\partial_{x_i} m_{\varepsilon}|^{a-2} \partial_{x_i} m_{\varepsilon} \) and integrating by parts over \( \Omega \), we obtain with the H"older and Young inequalities that

\[
\frac{d}{dt} \| \varphi |\partial_{x_i} m_{\varepsilon}|^{\frac{a}{2}} \|^2 = -\frac{4(a-1)}{a} \| \varphi \nabla |\partial_{x_i} m_{\varepsilon}|^{\frac{a}{2}} \|^2 - 4\varepsilon_{1} \left( \| \varphi \nabla |\partial_{x_i} m_{\varepsilon}|^{\frac{a}{2}} \|_{a} \| \partial_{x_i} m_{\varepsilon}|^{\frac{a}{2}} \|_{a} \right) - a\alpha \| \partial_{x_i} m_{\varepsilon}|^{\frac{a}{2}} \|^2 \leq C_{23}(a) \| \nabla \varphi \|_{2}^{2} \| \partial_{x_i} m_{\varepsilon}\|_{a}^{a} - C_{24}(a) \| \nabla \varphi \|_{2}^{2} \| \partial_{x_i} m_{\varepsilon}\|_{a}^{a} - C_{25}(a) \| \partial_{x_i} m_{\varepsilon}|^{\frac{a}{2}} \|_{a}^{a}. \tag{6.63}
\]

Owing to a Sobolev interpolation inequality it holds that

\[
\left\| m_{\varepsilon}^{\frac{1}{\gamma}} \right\|_{\frac{1}{\gamma - \frac{1}{2}}} \leq C_{20}(a) \left( \| \nabla m_{\varepsilon}^{\frac{1}{\gamma}} \| + \| m_{\varepsilon}^{\frac{1}{\gamma}} \| \right)^{N(1-\frac{1}{2})} \| m_{\varepsilon}^{\frac{1}{\gamma}} \|^{1-N(1-\frac{1}{2})} \text{ for } a \in \left[1, \frac{N}{N-1}\right]. \tag{6.64}
\]
Integrating (6.63) over \((0, t)\) and using (6.9), (6.12), (6.64) and the Hölder inequality, we thus obtain that
\[
\| \varphi \|_{\nabla m_{2} (t)}^2 \leq \| \varphi \|_{\nabla m_{2} (0)}^2 + C_{27} (a, T) \| \nabla m_{2} \|_{L^d}^{\frac{1}{2}} \left( \frac{N}{N + 1} \right)^{\frac{a - 1}{2}} - \frac{\hat{\gamma}}{2} \text{ for } a \in \left( 1, \frac{N}{N - 1} \right).
\] (6.65)

The first term on right-hand side of (6.65) doesn’t depend upon \(\varepsilon_1\), while the second one converges to zero for \(a \in \left( 1, \frac{N + 1}{N + 2} \right) \subseteq \left( 1, \frac{N}{N + 1} \right)\). Therefore, we obtain from (6.65) in the limit as \(\varepsilon_1 \to 0\) that
\[
\limsup_{\varepsilon_1 \to 0} \| \varphi \|_{\nabla m_{2} (t)}^2 \leq \| \varphi \|_{\nabla m_{2} (0)}^2 \leq \left( \frac{N + 2}{N + 1} \right)^{\frac{a}{2}} \text{ for } a \in \left( 1, \frac{N + 2}{N + 1} \right).
\] (6.66)

Since \(\varphi\) was an arbitrary cut-off function with \(\text{supp } \varphi \subset \text{int } \{ v \equiv 0 \}\), (6.66) yields that
\[
\limsup_{\varepsilon_1 \to 0} \| | \nabla m_{2} (t) \|_{L^d (\text{int } \{ v \equiv 0 \})}^2 \leq \| | \nabla m_{2} (0) \|_{\Omega}^2 \text{ for } a \in \left( 1, \frac{N + 2}{N + 1} \right).
\] (6.67)

Together with (6.12), (6.67) yields that
\[
\limsup_{\varepsilon_1 \to 0} \| | m_{2} (t) \|_{W^{1/2, 1} (\text{int } \{ v \equiv 0 \})} \leq C_{28} (\varepsilon_2).
\] (6.68)

### 7 Global existence for the original problem

In this section we aim to pass to the limit in (5.1) in order to obtain a solution of the original problem.

**Remark 7.1** (Vector notation). Let \(\{ \varepsilon_i, n_i \} \subset (0, 1), i = 1, 2, 3\), be three sequences. In this section, we make use of the following vector notation:
\[
n_{i; 3} := (n_i, \ldots, n_3), \quad \varepsilon_{n_{i; 3}} := (\varepsilon_i, n_i, \ldots, \varepsilon_3, n_3), \quad i = 1, 2.
\]

Owing to the estimates obtained in the preceding section, we are now in a position where we can establish a list convergences (see below) holding jointly for some sequences
\[
\varepsilon_i, n_i \to 0, \quad i = 1, 2, 3.
\]

**Convergence for the initial data**

Due to (5.9)-(5.11) it holds that
\[
m_{2, n, 0} \to m_0 \text{ in } L^1 (\Omega) \text{ and a.e. in } \Omega, \quad (7.1)
m_{e, n, 0} \to p_0 \text{ in } L^d (\Omega) \text{ and a.e. in } \Omega, \quad (7.2)
v_{2, n, 0}^{\frac{1}{2}} \to v_0^{\frac{1}{2}} \text{ in } L^2 (\Omega) \text{ and a.e. in } \Omega; \quad (7.3)
\]

**Convergence for \(\{ v_{\varepsilon n_{1; 3}} \} \)**

It holds that: due to (6.5), (6.31) and a version of the Lions-Aubin Lemma [36, Corollary 4]
\[
v_{\varepsilon n_{1; 3}}^{\frac{1}{2}} \to v^{\frac{1}{2}} \text{ in } L^2 (0, T; L^2 (\Omega)); \quad (7.4)
\]
due to (7.4)
\[
v_{\varepsilon n_{1; 3}}^{\frac{1}{2}} \to v^{\frac{1}{2}} \text{ a.e. in } (0, T) \times \Omega; \quad (7.5)
\]
due to (7.5)
\[
v_{\varepsilon n_{1; 3}} \to v \text{ a.e. in } (0, T) \times \Omega; \quad (7.6)
\]
due to (7.6) and the dominated convergence theorem
\[
v_{\varepsilon n_{1; 3}}^a \to v^a \text{ in } L^p ((0, T) \times \Omega) \text{ and a.e. in } (0, T) \times \Omega \text{ for all } a > 0, p \geq 1; \quad (7.7)
\]
due to (6.5), (7.4) and the Banach-Alaoglu theorem
\[
\nabla v_{\varepsilon n_{1; 3}}^{\frac{1}{2}} \to \nabla v^{\frac{1}{2}} \text{ in } L^2 (0, T; L^2 (\Omega)). \quad (7.8)
\]
Convergence for \( \{m_{\varepsilon n_1,3}\} \) in \((0, T) \times \{v_0 > 0\}\)

It holds that: due to (6.39), (6.56) and a version of the Lions-Aubin Lemma [36, Corollary 4]

\[
\ln \left(1 + \varepsilon_{n_1,3}^2 m_{\varepsilon n_1,3}\right) \rightarrow u \text{ in } L^1((0,T); L^1(\Omega));
\]  
(7.9)

due to (7.9)

\[
\ln \left(1 + \varepsilon_{n_1,3}^2 m_{\varepsilon n_1,3}\right) \rightarrow u \text{ a.e. in } (0,T) \times \Omega;
\]  
(7.10)

due to (7.10)

\[
\varepsilon_{n_1,3}^2 m_{\varepsilon n_1,3} \rightarrow e^u - 1 =: w \text{ a.e. in } (0,T) \times \Omega;
\]  
(7.11)

due to (7.6), (7.11)

\[
m_{\varepsilon n_1,3} \rightarrow \frac{w}{\varepsilon_{n_1,3}^2} =: m \text{ a.e. in } (0,T) \times \{v_0 > 0\};
\]  
(7.12)

due to (6.13), (7.12) and the Vitali convergence theorem

\[
m_{\varepsilon n_1,3} \rightarrow m \text{ in } L^1((0,T) \times \{v_0 > 0\}).
\]  
(7.13)

Convergence for \( \{m_{\varepsilon n_1,3}\} \) in \((0, T) \times \{v_0 = 0\}\)

It holds due to (6.61), (6.68) and a version of the Lions-Aubin Lemma [36, Corollary 4] that

\[
m_{\varepsilon n_1,3} \rightarrow m_{n_2,3} \text{ in } L^1((0,T) \times \text{int}\{v_{\varepsilon 3,n_3} = 0\}),
\]  
(7.14)

and so we may pass to the distributional limit in (6.60):

\[
\hat{c}_t m_{n_2,3} = -\alpha m_{n_2,3} \text{ in } \mathbb{R}^+ \times \text{int}\{v_{\varepsilon 3,n_3} = 0\},
\]  
(7.15a)

\[
m_{n_2,3} (0) = m_{\varepsilon n_1,3} (0) \text{ in } \text{int}\{v_{\varepsilon 3,n_3} = 0\}.
\]  
(7.15b)

Due to (7.1) and the continuous dependence of solutions of an ODE with smooth coefficients upon the initial data, it follows with (7.15b) that

\[
m_{n_2,3} \rightarrow m_{n_3} \text{ in } L^1((0,T) \times \text{int}\{v_{\varepsilon 3,n_3} = 0\})
\]  
(7.16)

and

\[
m_{n_3} = m \text{ a.e. in } (0,T) \times \text{int}\{v_{\varepsilon 3,n_3} = 0\} \cap \{v_0 = 0\},
\]  
(7.17)

where \( m \) solves

\[
\hat{c}_t m = -\alpha m \text{ in } \mathbb{R}^+ \times \{v_0 = 0\},
\]  
(7.18a)

\[
m(0) = m_0 \text{ in } \{v_0 = 0\}.
\]  
(7.18b)

Combining (7.14), (7.16)-(7.18), we conclude that

\[
m_{\varepsilon n_1,3} \rightarrow m \text{ in } L^1((0,T) \times \text{int}\{v_{\varepsilon 3,n_3} = 0\} \cap \{v_0 = 0\}),
\]  
(7.19)

hence also

\[
m_{\varepsilon n_1,3} \rightarrow m \text{ on } (0,T) \times \text{int}\{v_{\varepsilon 3,n_3} = 0\} \cap \{v_0 = 0\} \text{ in the measure.}
\]  
(7.20)

Together with property (5.12), (7.20) yields that

\[
\lim_{n_3 \rightarrow \infty} \lim_{n_2 \rightarrow \infty} \lim_{n_1 \rightarrow \infty} \left\{ \left| \|m_{\varepsilon n_1,3} - m\|_1 \geq \delta \right\} = 0 \text{ on } (0,T) \times \{v_0 = 0\} \text{ for all } \delta > 0.
\]  
(7.21)

Finally, combining (6.13), (7.21) and using the Vitali convergence theorem, we arrive at

\[
\lim_{n_3 \rightarrow \infty} \lim_{n_2 \rightarrow \infty} \lim_{n_1 \rightarrow \infty} \left\{ \|m_{\varepsilon n_1,3} - m\|_{L^1((0,T) \times \{v_0 = 0\})} = 0.
\]  
(7.22)
Convergence for \( p_{\varepsilon_{n;1}} \) in \((5.1b)-(5.1c)\)

We may consider \((5.1b)-(5.1c)\) together with the corresponding initial conditions as an abstract ODE system with respect to the variables \( p_{\varepsilon_{n;1}} \) and \( v_{\varepsilon_{n;1}} \) regarding \( m_{\varepsilon_{n;1}} \) as a parameter function:

\[
\frac{d}{dt} \begin{pmatrix} p_{\varepsilon_{n;1}} \\ v_{\varepsilon_{n;1}} \end{pmatrix} = G \left( \begin{pmatrix} p_{\varepsilon_{n;1}} \\ v_{\varepsilon_{n;1}} \end{pmatrix}, m_{\varepsilon_{n;1}} \right) \text{ in } L^1(\Omega),
\]

where the function \( G : ([0,C_p] \times [0,1]) \times \mathbb{R}_+^d \rightarrow \mathbb{R}_+^d \) is clearly globally Lipschitz. Here \( C_p \) is an upper bound for the family \( \{p_i\} \), compare (6.2). Using the standard abstract ODE theory in \( L^1 \), which states that the solutions depend continuously upon parameters and initial data, we conclude with (7.2)-(7.3) and (7.13), (7.22) that

\[
\begin{align*}
p_{\varepsilon_{n;1}} &\rightarrow p \text{ in } L^1((0,T) \times \{v_0 > 0\}), \\
p_{\varepsilon_{n;1}} &\rightarrow p \text{ a.e. in } (0,T) \times \{v_0 > 0\}, \\
\lim_{n \rightarrow \infty} \lim_{n \rightarrow \infty} \sup_{n \rightarrow \infty} \sup_{n \rightarrow \infty} \|p_{\varepsilon_{n;1}} - p\|_{L^1((0,T) \times \{v_0 = 0\})} = 0,
\end{align*}
\]

and \( m, p, v \) solve the original equations \((2.1b)-(2.1c)\) and satisfy the initial conditions in \( L^1 \)-sense, as stated in Definition 4.2.

Convergence in \((5.2)\)

In order to finish the proof of Theorem 4.5, it remains to check that the triple \((m, p, v)\), which we obtained above by means of our limit procedure, satisfies the weak formulation (4.1). For this purpose, we need to pass to the limit in the weak formulation \((5.2)\). Taking \( \varepsilon := \varepsilon_{n;1} \), we have that

\[
\int_0^T \int_\Omega m_{\varepsilon_{n;1}} \varphi \, dx \, dt = \int_0^T \int_\Omega \left( \varepsilon_{n;1} \varphi \Delta \varphi - I_{\varepsilon_{n;1}} \cdot \nabla \varphi + \varepsilon_{n;1} \Delta \psi \right) \, dx \, dt,
\]

where in order to shorten the notation we introduced

\[
I_{\varepsilon_{n;1}} := \left( \frac{\kappa_m \varepsilon_{n;1}}{1 + \varepsilon_{n;1} v_{\varepsilon_{n;1}}} + \frac{\kappa_v}{1 + \varepsilon_{n;1}} \right) \frac{2}{\varepsilon_{n;1}^2} \left( m_{\varepsilon_{n;1}} + 1 \right)^{\frac{3}{2}} \\
\cdot \left( \nabla \left( \frac{1}{2} \varepsilon_{n;1} m_{\varepsilon_{n;1}} + 1 \right)^{\frac{1}{2}} - (m_{\varepsilon_{n;1}} + 1)^{\frac{1}{2}} \nabla \varepsilon_{n;1} \right)
\]

\[
= \frac{\kappa_m \varepsilon_{n;1} v_{\varepsilon_{n;1}}}{1 + \varepsilon_{n;1} v_{\varepsilon_{n;1}}} \nabla m_{\varepsilon_{n;1}} + \frac{\kappa_v}{1 + \varepsilon_{n;1}} \nabla \varepsilon_{n;1}.
\]

Observe that the representations (7.27) and (7.28) coincide due to the chain and product rules. But for \( I_{\varepsilon_{n;1}} \), the convergence of the terms in (7.26) can be obtained with standard tools using (6.2), (6.13), (6.20), (7.1), (7.5), (7.6), (7.23). We thus leave these details aside and concentrate on the weak \( L^1 \)-limit for \( I_{\varepsilon_{n;1}} \). To start with, (6.22), (6.26) and (7.28) imply that

\[
\{ I_{\varepsilon_{n;1} } \} \text{ is uniformly integrable in } (0,T) \times \Omega.
\]

Hence, the Dunford-Pettis theorem applies and yields the existence of such limit:

\[
I_{\varepsilon_{n;1}} \rightarrow \tilde{I} \text{ in } L^1((0,T) \times \Omega).
\]

We claim that \( \tilde{I} \) can be obtained by simply dropping the index \( \varepsilon_{n;1} \) everywhere in (7.27). We observe that (7.27) admits the following reformulation:

\[
I_{\varepsilon_{n;1}} = I_1 \left( m_{\varepsilon_{n;1}}, p_{\varepsilon_{n;1}}, v_{\varepsilon_{n;1}} \right) \nabla \left( I_2 \left( m_{\varepsilon_{n;1}}, v_{\varepsilon_{n;1}} \right) \right) + I_2 \left( m_{\varepsilon_{n;1}}, p_{\varepsilon_{n;1}}, v_{\varepsilon_{n;1}} \right) \nabla \varepsilon_{n;1}.
\]
where $I_1, I_2 : \mathbb{R}^3 \to \mathbb{R}$, $I_3 : \mathbb{R}^2 \to \mathbb{R}$ are continuous functions. Since $I_1(\cdot, \cdot, 0) = I_2(\cdot, \cdot, 0) = 0$, it holds with (6.58), (7.31) that

$$I_{\varepsilon_{1:3}} = 0 \text{ a.e. in } (0, T) \times \{v_{\varepsilon_0} = 0\}. \tag{7.32}$$

Combining (7.29), (7.32) with (6.58), (7.31) that

$$D$$

we define the diffusion coefficient

The discretization in space now takes place with the aid of two-point flux approximations as in [13]. First

Further, we have due to (7.5), (7.12), (7.24), and the continuity of

$$I$$

where

$$I$$

we arrive at

$$\nabla \left( I_3 \left( m_{\varepsilon_{1:3}}, v_{\varepsilon_{1:3}} \right) \right) \to \nabla (I_3(m,v)) \text{ in } L^1((0,T) \times \{v_0 > 0\}). \tag{7.37}$$

Finally, combining (7.8), (7.33), (7.34), (7.37) and using Lemma A.3, we arrive at

$$I_1 \left( m_{\varepsilon_{1:3}}, p_{\varepsilon_{1:3}}, v_{\varepsilon_{1:3}} \right) \nabla \left( I_3 \left( m_{\varepsilon_{1:3}}, v_{\varepsilon_{1:3}} \right) \right) + I_2 \left( m_{\varepsilon_{1:3}}, p_{\varepsilon_{1:3}}, v_{\varepsilon_{1:3}} \right) \nabla^2 v_{\varepsilon_{1:3}} \to I_1(m,p,v) \nabla (I_3(m,v)) + I_2(m,p,v) \nabla v^2 \text{ in } L^1((0,T) \times \{v_0 > 0\}).$$

The proof of Theorem 4.5 is thus completed.

### 8 Numerical Simulations

We discretize the PDE-ODE-ODE system (2.1) using a local mass conservative and monotone finite volume method. We use the software package Dune [3, 4, 6, 7] and consider on the domain $\Omega = (0,1)^2$ the structured quadrilateral grid Yaspgrid therein.

#### 8.1 Implementation

Let $C$ be the set of computational cells in the grid and denote by $E(c)$ the (inner) edges of the grid surrounding a cell $c$. Then we approximate the vector $u = (m,p,v)^T$ in the space $P_0^D$, so the restriction of $u$ on a computational cell $c$ is a constant vector. Due to the nonlinearity of the system it is favorable to employ IMEX-splitting schemes, so we may handle one part of the system implicitly and another part explicitly. The reaction part

$$\hat{c}_1 \dot{u} = \left( \begin{array}{c} -\alpha \hat{u}_1 + \beta \hat{u}_2 \hat{u}_3 \\ \alpha \hat{u}_1 - \beta \hat{u}_2 \hat{u}_3 + \mu_p \hat{u}_2 (1 - (\hat{u}_1 + \hat{u}_2) - \eta \hat{u}_3) \\ \mu_p \hat{u}_2 (1 - \hat{u}_2) - \lambda \hat{u}_3 \hat{u}_1 \end{array} \right) = f(\hat{u})$$

of the system (2.1) is cell-wise a simple ODE, which we solve via an explicit 4th order Runge-Kutta method.

For the convection-diffusion part we have

$$\hat{c}_2 \dot{u} = \left( \begin{array}{c} \nabla \cdot \left( \frac{\kappa_m \hat{u}_3 (1 + \hat{u}_1 + \hat{u}_2)}{1 + \hat{u}_1 + \hat{u}_2} \nabla \hat{u}_1 - \frac{\kappa_m \hat{u}_3 (1 + \hat{u}_1 + \hat{u}_2)^2}{1 + \hat{u}_1 + \hat{u}_2} \nabla \hat{u}_3 \right) \hat{u}_1 \\ 0 \\ 0 \end{array} \right) = 0. \tag{8.1}$$

The discretization in space now takes place with the aid of two-point flux approximations as in [13]. First we define the diffusion coefficient $D(u) = \frac{\kappa_m \hat{u}_3 (1 + \hat{u}_1 + \hat{u}_2)}{1 + \hat{u}_1 + \hat{u}_2}$ and the drift velocity $V(u) = \frac{\kappa_m \hat{u}_3 (1 + \hat{u}_1 + \hat{u}_2)^2}{(1 + \hat{u}_1 + \hat{u}_2)^2}$. The
convection velocity \( V(u) \nabla u_2 \) and the diffusion term \( D(u) \nabla u_1 \) have both the same structure, therefore we use the same space discretization. Hence we will only present the diffusive flux discretization in detail. We may integrate (8.1) over a computational cell \( c \) by employing the Gauß theorem

\[
\partial_t u|_c = \sum_{c \in E(c)} F^e_c + V^e_c (u_1)_t^e,
\]

where \( F^e \) is the approximation of the diffusive flux and \( V^e \) is an approximation of the drift velocity though an edge \( e \). The symbol \( (u_1)_t^e \) stands for a simple upwinding scheme [13]. To get a locally mass conservative method, we require that for each edge \( e \) between cells \( c \) and \( c' \) we have \( F^e_c + F^e_{c'} = 0 \), as well as \( V^e_c + V^e_{c'} = 0 \). This gives the possibility to resolve the edge variables and for an edge \( e \) between \( c \) and \( c' \) we have

\[
F^e_c = \frac{D(u)|_c D(u)|_{c'}}{D(u)|_c + D(u)|_{c'}} ((u_1)|_c - (u_1)|_{c'}) \frac{2|e|}{d(c,c')},
\]

The drift velocity is computed in the same way. Now denote by \( \mathcal{F}(u) \) the space discretized convective and diffusive flux terms and let the timestep of our scheme be \( \Delta t \). Then we resolve the reaction terms explicitly (these are cell-wise ODEs) with a Runge-Kutta method (denoted by its numerical flux \( \Phi_{RK} \)), while the convection-diffusion part will be handled via an implicit Euler step:

\[
u^{k+1} + \Delta t \mathcal{F}(u^{k+1}) = u^k + \Phi_{RK}(u^k).
\]

We solve the previous equation (8.2) by the classical Newton method.

### 8.2 Results

We have to select initial conditions. Therefore we assume a grate-like initial condition for \( v \) and define the following sets:

\[
\begin{align*}
S_1 &= \{x \in \mathbb{R}^2 | x_2 \in (0.35, 0.45) \} \\
S_2 &= \{x \in \mathbb{R}^2 | x_2 \in (0.7, 0.8) \} \\
S_3 &= \{x \in \mathbb{R}^2 | |x_1 - \hat{x}| < 0.01, \text{ for } \hat{x} \in \{0.4, 0.45, 0.5, 0.55, 0.6, 0.65\} \} \\
S_4 &= \{x \in \mathbb{R}^2 | |x_1 - x_2 - \hat{x}| < 0.01, \text{ for } \hat{x} \in \{-0.2, -0.1, 0.0\} \} \\
S_5 &= \{x \in \mathbb{R}^2 | |x_1 - 0.5 \cdot x_2 - \hat{x}| < 0.01, \text{ for } \hat{x} \in \{0.5, 0.6\} \}
\end{align*}
\]

Then we select the intuitive initial value for the tissue fibers as

\[
\bar{v}_0 = 0.9 \cdot 1_{\left\{x \in \bigcup_{i=1}^5 S_i\right\}}.
\]

Now we need to think about the initial conditions for the tumor variables. We observe that migrating tumor cells (variable \( m \)) will pass into the proliferating regime if no tissue is available (at least it is highly improbable to find a migrating cell in absence of tissue fibers). This is to be incorporated into the initial condition for \( m \). For the initial population of proliferating tumor cells, however, we do not have the tissue dependence, so we may also select initial conditions for \( p \) in absence of tissue. Due to the fact, however, that proliferating cells do not migrate (go-or-grow dichotomy), we have to assume a small compact support. We use random perturbations of the initial conditions to simulate the effect of non-homogeneous tumor cell distributions. With all these considerations we select the initial conditions for the cell variables in the form

\[
\begin{align*}
m_0(x) &= 1_{\{|x - x_0|^2 < 0.02\}} \cdot \min(0.5 \cdot \Psi_{0.05}(|x - x_0|^2 + d), 1.0) \cdot 1_{\left\{x \in \bigcup_{i=1}^5 S_i\right\}} \\
p_0(x) &= 1_{\{|x - x_0|^2 < 0.01\}} \cdot \min(0.8 \cdot \Psi_{0.1}(|x - x_0|^2 + d), 1.0),
\end{align*}
\]

where \( x_0 = \left(\frac{1}{2}, \frac{1}{2}\right)^T \) and

\[
\Psi_\sigma(s) = \frac{1}{2\pi\sigma} \exp\left(-\frac{s}{2\sigma^2}\right).
\]

The symbol \( d \) in the initial conditions stands for the random perturbation. We used here a uniform \( \mathcal{U}(-0.01, 0.04) \) distribution. We are not done in the initial values section, because due to the dissolving of the tissue fibers caused by the migrating cells, we have to modify the initial values for \( v \) a bit:

\[
v_0 = \max\left(\bar{v}_0 - (m_0 + p_0), 0.0\right).
\]
The remaining task is to select the parameters involved in the model. Some of them are available from literature, but for the diffusion coefficient $\kappa_m$ and the haptotactic coefficient $\kappa_v$ we select higher values for the diffusion (compared to the previous papers [11, 38, 44]), as the migratory behavior of the cells is diffusion dominated. The tissue is distributed in a quite inhomogeneous way, however on a tissue fiber (or fiber bundle) the material is homogeneous, meaning that the tissue gradient $\nabla v$ and whence the haptotaxis is vanishing. Nevertheless, haptotaxis is not negligible, as it describes the guidance of cell migration by the tissue fibers (dissolved or not). The concrete parameter selection is summarized in Table 1.

Table 1: Parameters used in the model.

The grid we use is a triangulation of the unit cube in two dimensions, with 200 cells in each direction. So we also have to select a small time step $\Delta t$. In our calculations we used $\Delta t = 0.01$ and simulated the equation up to time 1000.

Figure 1 shows the simulation results. The comparison between the evolution of migrating and proliferating cells elicits the expected behavior: the migrating cells are predominant in the regions with high tissue density (it can be actually seen how they follow the tissue fibers -and degrade them), while the proliferating cells occupy the regions with very low tissue density. This is in agreement with the go-or-grow dichotomy and the degeneracy of the diffusion coefficient in equation (2.1a): For $v = 0$ (no tissue) the migrating cells stop and become proliferating cells. Moreover, the model is able to reproduce the often irregular shape of a tumor and the associated spread of cancer cells exhibiting various infiltrative (INF) patterns. According to the Japanese gastric association group [2], the latter provide a way to classify local invasiveness and tumor malignancy. In particular, Figure 1 exhibits some small ‘islands’ of cell aggregates, transiently isolated from the main tumor, which then grow and merge again with the neoplastic cell mass. That tumor cells have an infiltrative spread, form finger patterns, and closely follow the specific tissue structure has been recognized for many types of cancer; perhaps the most prominent example featuring these characteristics are gliomas, see e.g. [9, 17, 19, 21]. This behavior has also been confirmed by several models in a different mathematical framework, but still relying on the go-or-grow dichotomy and leading to related reaction-diffusion-taxis equations [11, 23]. Like those models, the present setting allows to account for tumor heterogeneity w.r.t. the migratory/proliferative phenotypes of the constituent cells. As mentioned in the Introduction, this heterogeneity also reflects in the differentiated therapeutic response, an essential issue in therapy planning and assessment. Including therapy effects like e.g., in [38] can be easily addressed in this context as well. While current biomedical imaging only allows to determine the gross tumor volume, such models open the way to provide an (although imperfect) estimation of the tumor composition upon relying on the patient-specific tissue architecture and to correspondingly predict the extent of the neoplastic tissue.

Another interesting observation is that the amount of migrating cells increases with advancing time. This might suggest a possible blow-up; we recall that this issue remains open from an analytical point of view.

Appendix A

In this section we collect several auxiliary results on member-by-member products used above. We begin with a lemma which deals with the uniform integrability of member-by-member products.

**Lemma A.1** (Uniform integrability for products). Let $\Omega$ be a measurable subset of $\mathbb{R}^N$ with finite measure and $I$ be some set. Let $(f_i)_{i \in I}, (g_i)_{i \in I} \subset L^2(\Omega)$ be two families such that $\{f_i^2\}_{i \in I}$ is uniformly integrable and $\{g_i\}_{i \in I}$ is uniformly bounded in $L^2(\Omega)$. Then the family $\{f_i g_i\}_{i \in I}$ of member-by-member products is uniformly integrable.

This well-known property can be readily proved by using the definition of the uniform integrability. We leave the details to the reader. The following lemma is a generalization of the Lions lemma [29, Lemma 1.3] and the known result on weak-strong convergence for member-by-member products.
Figure 1: Simulation results

(a) Initial condition. From left to right: migrating cells $m$, proliferating cells $p$, tissue $v$, overall tumor $c = m + p$.

(b) Simulation at time 200

(c) Simulation at time 400

(d) Simulation at time 600
Lemma A.2 (Weak-a.e. convergence, [44]). Let $\Omega$ be a measurable subset of $\mathbb{R}^N$ with finite measure. Let $f_n, g_n : \Omega \rightarrow \mathbb{R}$, $n \in \mathbb{N}$ be measurable functions and $f, g, g_n \in L^1(\Omega)$, $n \in \mathbb{N}$. Assume further that $f_n \rightarrow f$ a.e. in $\Omega$ and $g_n \rightarrow g$. Then, it holds that $\xi = fg$ a.e. in $\Omega$.

As was observed in [44], a similar result holds for sums of member-by-member products:

Lemma A.3 (Weak-a.e. convergence for sums, [44]). Let $\Omega$ be a measurable subset of $\mathbb{R}^N$ with finite measure and let $L \in \mathbb{N}$. Let $f^l, f^l_n : \Omega \rightarrow \mathbb{R}$, $n \in \mathbb{N}$, $l \in \{1, ..., L\}$, be measurable functions and $g^l, g^l_n \in L^1(\Omega)$, $n \in \mathbb{N}$, $l \in \{1, ..., L\}$. Assume further that $f^l_n \rightarrow f^l$ a.e. in $\Omega$ and $g^l_n \rightarrow g^l$. Then, it holds that $\xi = \sum_{l=1}^{L} f^l g^l$ a.e. in $\Omega$.

Remark A.4. Observe that, in Lemma A.3, it is not required that the sequences $\{f^l_n, g^l_n\}_{n \in \mathbb{N}}$ themselves are convergent for $l \in \{1, ..., L\}$, but only their sum $\{\sum_{n=1}^{L} f^l_n g^l_n\}_{n \in \mathbb{N}}$. Thus, the result is applicable in the cases where the convergence of individual sequences is either false or unknown.
