AN INTRODUCTION TO THE NONLINEAR BOLTZMANN-VLASOV EQUATION

HELMUT NEUNZERT

PREPRINT NO 28

Lectures given at the international summerschool 'Kinetic Theories and Boltzmann Equations' of C.I.M.E. in Montecatini (Italy), June 1981.
AN INTRODUCTION TO THE NONLINEAR BOLTZMANN-VLASOV EQUATION

H. Neunzert, Universität Kaiserslautern, W.-Germany

1. The derivation of the modified Vlasov equation

The Vlasov equation in its simplest form describes the behaviour of a gas consisting of a large number of identical particles moving according to the laws of classical mechanics and interacting by a potential, which is proportional to the mass (or charge respectively) of the particles and which is - that is the main point - only weakly singular.

"Weakly singular" means precisely: The force, exerted by a particle \( x \) on a particle at \( y \), both of mass \( m \), has the form \( m^2 G(x,y) \), where \( G \) might become singular for \( x=y \) only in a way, that at

\[
\int_{\mathbb{R}^3} G(x,y) \varphi(y) \, dy
\]

exists for all \( x \in \mathbb{R}^3 \), \( \varphi \in L^1(\mathbb{R}^3) \).

The most typical examples are

\[
(1) \quad G(x,y) = -\gamma \frac{1}{||x-y||} = -\gamma \frac{x-y}{||x-y||^3}
\]

with \( \gamma > 0 \), if \( m^2 G \) is the gravitational force and with \( \gamma < 0 \), if \( m^2 G \) is the Coulomb force.

The Vlasov equation has the form

\[
(2) \quad \frac{\partial f}{\partial t} + \langle v, \nabla_x f \rangle + \int_{\mathbb{R}^6} G(x,y)f(t,y,v) \, dydv, \langle \; \nabla v f \rangle = 0
\]

and is assumed to describe for \( G \) given in (1) the behaviour of a stellar gas, if \( \gamma > 0 \) or the behaviour of an electron gas, if \( \gamma < 0 \). For the stellardynamic case (2) was already considered by Jeans in 1915, while Vlasov introduced that equation for the plasmaphysical case in 1938.

Our aim is to investigate, in which sense the Vlasov equation describes the behaviour of a system of \( N \) identical particles, which move under the influence of their mutual interaction forces.

If we normalize the total mass (or charge) to 1, each particle has
mass (charge) $\frac{1}{N}$ and the state is described just by giving the positions and velocities of the particles, i.e. by

$$p_i := (x_i, v_i) \in \mathbb{R}^6, \ i = 1, \ldots, N.$$  

The motion is then governed by Newton's law

$$\dot{x}_i = v_i,$$

$$\ddot{v}_i = \frac{1}{N} \sum_{j=1}^{N} G(x_i, x_j).$$

So, given the state $\omega_N = (p_1, \ldots, p_N)$ at time $0$, we get the state $\omega_N(t) := (p_1(t), \ldots, p_N(t))$ at time $t$ by solving the initial value problem for (3) with $p_i(0) = \dot{p}_i$, $i = 1, \ldots, N$. Such a solution might exist only for finite time - for $m^2G$ being the gravitational force (3) represents the N-body-problem of celestial mechanics and has therefore only local solutions. Even more, the time interval of existence certainly depends on $N$ and its length might tend to $0$ if $N$ tends to infinity.

In order to get rid of these difficulties we assume here, that $G$ is not singular, but bounded and continuous. That can be achieved by a smooth cut-off of the potential or another mollifying procedure, for example by substituting the original $G$ (which is weakly singular) by

$$G_\delta(x, y) := \int_{\mathbb{R}^3} G(x, z) \omega_\delta(z - y) dz,$$

with the "mollifier" $\omega_\delta$ defined by

$$\omega_\delta(x) := \begin{cases} 0 & \text{for } ||x|| > \delta \\ c_\delta \exp(-1 + \frac{||x||^2}{\delta^2}) & \text{for } ||x|| < \delta \end{cases}$$

where $c_\delta$ is such that $\int_{\mathbb{R}^3} \omega_\delta dx = 1$.

Or by substituting the special $G(x, y) = \frac{x - y}{||x - y||^3}$ by

$$G_\delta(x, y) = \frac{x - y}{(||x - y||^2 + \delta)^{3/2}}.$$

$G_\delta$ is certainly bounded and continuous; we will write again $G$ for $G_\delta$ in that lecture. Equation (2) with $G_\delta$ instead of $G$ is called the "modified Vlasov equation". For bounded and continuous $G$ the initial value problem for (3) has a global solution; $\omega_N(t)$ is defined for all $t \in \mathbb{R}$. 

We want to compare now \( \omega_N(t) \) with a function \( f(t, \cdot) : \mathbb{R}^6 \to \mathbb{R} \), which is a solution of the Vlasov equation.

Let us begin with \( t = 0 \): We have to compare \( \omega_N(0) = \delta^0_N \) with \( f(0, \cdot) = \bar{f} \), where \( \bar{f} \) is the initial value for the Vlasov equation (2). In order to be able to compare \( \delta^0_N = \{ \delta^0_{p_1}, \ldots, \delta^0_{p_N} \} \) and \( f \), we have to interpret both as mathematical objects of the same kind. Both describe mass (or charge) distributions. Mass distributions can be described by measures. Therefore interpret both \( \delta^0_N \) and \( \bar{f} \) as Borel measures.

(a) \( \delta^0_N \) is substituted by the discrete measure

\[
\delta^0_{\omega_N} := \frac{1}{N} \sum_{j=1}^{N} \delta^0_{p_j}
\]

where \( \delta^0_{p_j} \) is the usual Dirac measure concentrated on \( p_j \). \( \delta^0_N \) has total mass 1; therefore it is called a probability measure.

(b) \( \bar{f} \) is supposed to be a positive function on \( \mathbb{R}^6 \) with

\[
\int_{\mathbb{R}^6} \bar{f} \, dx \, dv = 1.
\]

Therefore \( \bar{f} \) might be interpreted as the density (with respect to the normal 6-dimensional Lebesgue measure) of a probability measure \( \bar{\mu} \):

\[
\bar{\mu}(M) := \int_M \bar{f} \, dx \, dv \quad \text{for every Borel set } M.
\]

So instead of using \( \omega_N \) to describe the state of the N-particle system and \( f \) to describe the initial condition for (2), we use the probability measures \( \delta^0_{\omega_N} \) and \( \bar{\mu} \). We want to mention, that in spite of having probability measures there is no stochastic element in the description - we only have normalized the total mass.

We write \( M \) for the set of all probability measures on \( \mathbb{R}^6 \). The best method to compare \( \delta^0_{\omega_N} \) and \( \bar{\mu} \) will be provided by a metric in \( M \).

So we have to look for a metric in \( M \). But there is one condition such a metric should fulfill. There is a natural topology in \( M \), the weak\(^* \)-topology, which I describe by the corresponding weak convergence in \( M \):
\((\mu_n)_{n \in \mathbb{N}}\) converges weakly to \(\mu\), \(\mu_n \rightharpoonup \mu\), if and only if
\[
\lim_{n \to \infty} \int_{\mathbb{R}^6} \varphi \, d\mu_n = \int_{\mathbb{R}^6} \varphi \, d\mu \quad \text{for all bounded continuous } \varphi.
\]

Now it is important, that a metric \(\rho\) generates the weak convergence:
\[
\lim_{n \to \infty} \rho(\mu_n, \mu) = 0 \quad \text{if and only if } \mu_n \rightharpoonup \mu.
\]

We have several choices for \(\rho\), but not every choice is convenient for our purposes.

(1) There is the so-called "bounded Lipschitz distance" \(\rho_1\), defined by
\[
\rho_1(\mu, \nu) := \sup_{\varphi \in \mathcal{D}} \left| \int \varphi \, d\mu - \int \varphi \, d\nu \right|
\]
where \(\mathcal{D} = \{ \varphi : \mathbb{R}^6 \to [0,1], \left| \varphi(P) - \varphi(Q) \right| \leq \| P - Q \| \}
\text{for all } P, Q \in \mathbb{R}^6 \}.

(II) Dobrushin and Braun-Hepp used the Wasserstein-metric \(\tilde{\rho}\), defined as follows:
Consider the class \(\mathcal{C}\) of measures \(\sigma\) on \(\mathbb{R}^{12}\), such that
\[
\sigma(M \times \mathbb{R}^6) = \mu(M), \quad \sigma(\mathbb{R}^6 \times N) = \nu(N).
\]
Then
\[
\tilde{\rho}(\mu, \nu) = \inf_{\sigma \in \mathcal{C}} \int_{\mathbb{R}^{12}} \min \{ \| P - Q \|, 1 \} \, d\sigma(P, Q).
\]

(III) The most simple possible choice is the "discrepancy", defined by
\[
D(\mu, \nu) := \sup_{R \in \mathcal{R}} \left| \mu(R) - \nu(R) \right|
\]
where \(\mathcal{R}\) is the class of all subsets of \(\mathbb{R}^6\) of the form \(\{ P \in \mathbb{R}^6 \mid P \preceq Q \}\) with arbitrary but given \(\preceq\) and the usual semiorde in \(\mathbb{R}^6\).

But while \(\rho_1, \tilde{\rho}\) generate the weak convergence, this is not true for \(D\).

Only for absolutely continuous measure \(\nu\) is it true, that
\[
\mu_n \rightharpoonup \mu \iff D(\mu_n, \mu) \to 0.
\]
Therefore we have to be careful in using the discrepancy and we prefer \( \rho_1 \) to work with.

Now suppose we have a sequence of \( N \)-particle systems \( \omega_N \) with \( N \) increasing and an initial distribution \( \hat{\rho} \), so that

\[
\lim_{N \to \infty} \rho_1(\delta_{\omega_N}, \hat{\rho}) = 0.
\]

We solve, for each \( N \), the initial value problem for (3) with

\[
P_1(0) = \rho_N(1), \quad \text{where} \quad \omega_N = \{\rho_1^N, \ldots, \rho_N^N\}
\]

and get \( \omega_N(t) = \{\rho_1^N(t), \ldots, \rho_N^N(t)\} \) or correspondingly \( \delta_{\omega_N}(t) \).

On the other hand, let us assume, that \( f(t, \cdot) \) is a solution of the initial value problem for (2) with \( f(0, \cdot) = \hat{\rho} \), where \( \hat{\rho} \) is the density of \( \hat{\rho} \). (We return to the question of existence and uniqueness of the solution of that problem later.)

It follows immediately from (2), that

\[
\int_{\mathbb{R}^6} f(t, P) dP = \int_{\mathbb{R}^6} \hat{f}(P) dP = 1
\]

and \( f(t, P) \geq 0 \) for all \( t \geq 0 \). So \( f(t, \cdot) \) is again the density of a probability measure \( \mu_t \).

We are now able to formulate the notion "derivation of the Vlasov equation".

**Definition:** We call the Vlasov equation (2) "strictly derivable in \([0, T]\)" if for every solution \( \mu_t \) of the initial value problem for (2) with initial condition \( \hat{\rho} \)

\[
\lim_{N \to \infty} \rho_1(\delta_{\omega_N(t), \mu_t}) = 0 \quad \text{holds, if}
\]

\[
\lim_{N \to \infty} \rho_1(\delta_{\omega_N}, \hat{\rho}) = 0.
\]

**Remark:** It is clear that the definition depends on what we call a solution. If we allow a solution to be a weak solution, the definition is even stronger. On the other hand, the strong derivability
of the Vlasov equation with respect to a certain class of solutions
gives you also a hint what kind of solutions are physically meaning-
ful.

Now the question is: What conditions should be fullfilled by $G$,
so that (2) is strictly derivable? The answer is

**Theorem 1:** If $G$ is bounded, globally Lipschitz continuous, then (2)
is strongly derivable (with respect to a class of very
weak "measure solutions", which will be defined in the
following sketch of the proof).

**Sketch of the proof:** We put things in a more general setting. Let

$$
\mu_t : t \mapsto \mu_t \in M, \ t \in [0,T]
$$

be a weakly continuous measure valued function (weakly continuous
means that $t \mapsto \int \varphi \, d\mu_t$ is continuous for any bounded, continuous
$\varphi$).

We denote the set of these functions by $C_M$. Let us assume, that for
any $\mu \in C_M$ there is defined a six-dimensional time depending vector-
field

$$
(t, P) \mapsto V[\mu](t, P) \in \mathbb{R}^6, \ t \in [0,T], \ P \in \mathbb{R}^6.
$$

In case of (2), this vectorfield is given by

$$
V[\mu](t, x, v) = \begin{pmatrix}
    v \\
    \int_{\mathbb{R}^6} G(x, y) d\mu_t(y, v)
\end{pmatrix}
$$

(remember, that $\int_{\mathbb{R}^6} G(x, y) d\mu_t(y, v) = \int_{\mathbb{R}^6} G(x, y) f(t, y, v) dy dv$.

$V[\mu]$ has to satisfy two conditions, the first of which reads

(I) $V[\mu](t, P)$ should be continuous in $t$ and globally Lipschitz
continuous in $P$ (with Lipschitz constant $L$).

This is true for $V$ given by (7), since $\mu$ is weakly continuous,
$G(x, \cdot)$ is continuous for each $x$ and $G(\cdot, y)$ is globally Lipschitz
continuous.

If (I) is true, the initial value problem for the characteristic
equations
(8) \[ \dot{p} = V[u_*](t, p), \quad P(s) = \frac{\partial}{\partial s} \]

has a unique globally existing solution, which we denote by

\[ P(t) = T_{t,s}[u_*]P. \]

\[ T_{t,s} \] is bijective and \( T_{s,s}^{-1} = \text{id} \), \( T_{t,s}^{-1} = T_{s,t} \).

Now we consider the "fix point equation"

(9) \[ u_t = \frac{\partial}{\partial t} T_{t,0}[u_*], \quad t \in [0, T] \]

which is to interpret as

\[ u_t(M) = \int_0^T (T_{t,0}[u_*])M \quad \text{for every Borel set } M \in \mathbb{R}^6. \]

(9) is a measure theoretic formulation of (2), when \( V \) is given by (7) as the following lemma shows:

**Lemma:** If \( \frac{\partial}{\partial t} \) is absolutely continuous with density \( f \), then any solution \( u_t \) of (9) is absolutely continuous with density \( f(t, \cdot) \), which is a weak solution (in the sense defined by Lax for conservation laws) of the initial value problem

(10) \[ \frac{\partial f}{\partial t} + \text{div}_p(f \cdot V) = 0 \]

\[ f(0, \cdot) = f \]

**Remarks:**

1. If \( V \) is given by (7), equation (10) is the Vlasov equation (2).

2. A weak solution of (10) is defined to be a function \( f \) with

   (i) \( f(t, \cdot) \) is weakly continuous in \([0, T]\)

   (ii) for all test functions \( w \in C^1([0, T] \times \mathbb{R}^6) \) with \( \text{supp} w \subset [0, T] \times K \), \( K \) compact in \( \mathbb{R}^6 \), the equation

(11) \[ \int_0^T \int_{\mathbb{R}^6} \left[ \frac{\partial w}{\partial t} + V \cdot \text{grad}_p w \right] dp dt + \int_{\mathbb{R}^6} w(0, \cdot) \cdot df = 0 \]

holds. \( f \) is a classical solution of (10), if \( \frac{\partial}{\partial t} \) and \( V \) is sufficiently smooth.
Remarks on the proof of the Lemma: The main point is to prove that \( \mu_t \) is absolutely continuous, if \( \mu^0 \) is. But that follows by a rather unknown statement of Rademacher from 1916, that \( \mu \circ T^{-1} \) is absolutely continuous together with \( \mu \), if \( T \) is a bijective measurable mapping and \( T^{-1} \) is locally Lipschitz continuous. So putting \( T = T_0, t [ \mu ] \), \( \mu = \bar{\mu} \), the absolute continuity of \( \mu_t \) follows. The rest is essentially done by direct calculation.

The lemma shows, that (9) is a reasonable generalization of (2). But (10) includes also the N-body problem given by (3):

If we put \( \tilde{\mu}_t = \delta_{\omega_N}(t) \), then
\[
\int_{\mathbb{R}^d} G(x,y) d\tilde{\mu}_t(x) = \frac{1}{N} \sum_{j=1}^{N} G(x,x_j(t))
\]

and \( \bar{P}_i(t) \) is given as the solution of
\[
P = V[\delta_{\omega_N}(\cdot)](t,P), \quad P(0) = \delta_{P_i}, \quad i = 1, \ldots, N
\]

where \( V \) has the form (7). It follows by (8), that

\[
\dot{P}_i(t) = T_{t,0}[\delta_{\omega_N}(\cdot)] P_i^0
\]

Therefore a solution of the N-body problem (3) is a solution of equation (12) and (12) now is equivalent to

\[
\delta_{\omega_N}(t) = \delta_{\omega_N} \circ T_{0,0}[\delta_{\omega_N}(\cdot)]
\]

which is just (9) with \( \bar{\mu} = \delta_{\omega_N} \). To verify the last equivalence of (12) and (13), just calculate for an arbitrary Borel set \( M \)

\[
\delta_{\tilde{P}_i}(t)(M) = \delta_{T_{t,0}[\delta_{\omega_N}(\cdot)]} P_i^0(M)
\]

\[
= \begin{cases} 
1 & \text{if } T_{t,0}[\delta_{\omega_N}(\cdot)] P_i^0 \in M \\
0 & \text{else} 
\end{cases}
\]

\[
= \delta_{\bar{P}_i}(T_{0,0}[\tilde{\mu}_N(\cdot)](M) = \delta_{\bar{P}_i}(T_{0,0}[\delta_{\omega_N}(\cdot)](M).
\]

Summing up all \( i \) and dividing by \( N \) gives (13).
Conclusion: Both, the discrete N-body problem as well as the initial value problem for the Vlasov equation are special cases of equation (9), which correspond to different initial distributions $\delta_0$ and $\delta_0^{\omegaN}$ respectively. Our aim is to compare the solutions of these two special cases: We have to prove, that the solution of (9) is continuously depending on the initial data $\delta_0$, i.e. that $\delta_0^{\omegaN}(t) \rightarrow \mu_t$ if $\delta_0 \rightarrow 0$ for $N \rightarrow \infty$.

Now we need the second condition on $V$.

(II) The mapping $V: \mu \rightarrow V[\mu.]$ for $\mu \in C_M$ is Lipschitz continuous in the following sense:

$$\int_{\mathbb{R}^6} ||V[\mu.](t,P) - V[\nu.](t,P)|| \, d\nu_t(P) \leq K \rho_1(\mu_t, \nu_t)$$

for fixed $K$ and all $\mu, \nu \in C_M$.

That condition (II) is fulfilled by $V$ given in (7):

$$||V[\mu.](t,P) - V[\nu.](t,P)|| = \left\| \int_{\mathbb{R}^6} G(x,y) (d\nu_t(y,v) - d\nu_t(y,v)) \right\|,$$

where $B$ is the bound for $\|G(x,y)\|$ and $L$ the Lipschitz constant of $G$ (and $V$) (remember, that $\int_{\mathbb{R}^6} (d\nu_t - d\nu_t) = 0$, since $\mu_t$ and $\nu_t$ are probability measures).

Now $\frac{G(x,\cdot) + B}{2LB}$ is for each $x$ in class $D$ used in definition (4) if $L \geq 1$; therefore we get

$$||V[\mu.](t,P) - V[\nu.](t,P)|| \leq 2LB \rho_1(\mu_t, \nu_t).$$

Since the right hand side is independent of $P$ and $\theta_0$ is again a probability measure, we get (14) with $K = 2LB$.

The rest of the proof of theorem 1 is as follows, where we write $\tilde{\nu}$ for $\delta_0$, $\nu_t$ for $\delta_0^{\omegaN}(t)$:
\[
\rho_1(\mu^v, v^v) = \rho_1(\mu^\Omega, T_0, t[\mu^v], \mu^\Omega, T_0, t[v^v]) \\
= \rho_1(\mu^\Omega, T_0, t[\mu^v], \mu^\Omega, T_0, t[v^v]) + \rho_1(\mu^\Omega, T_0, t[v^v], \mu^\Omega, T_0, t[v^v])
\]

The first term on the right hand side might be estimated by using definition (4).

\[
\rho_1(\mu^\Omega, T_0, t[\mu^v], \mu^\Omega, T_0, t[v^v]) = \sup_{\varphi \in D} \int_{\mathbb{R}^6} |\varphi d(\mu^\Omega, T_0, t[\mu^v]) - \varphi d(\mu^\Omega, T_0, t[v^v])| \\
= \sup_{\varphi \in D} \int_{\mathbb{R}^6} \left| (\varphi \circ T_{t,o}[\mu^v]) - \varphi \circ T_{t,o}[v^v] \right| d\mu_0
\]

(since \(\varphi \in D\))

\[
\leq \sup_{\mathbb{R}^6} \int \|T_{t,o}[\mu^v] - T_{t,o}[v^v]\| d\mu_0 =: \lambda(t)
\]

Now \(T_{t,o}[\mu^v]P, T_{t,o}[v^v]P\) are solutions of the initial value problems

\(\dot{p} = \mathcal{V}[\mu^v](t,p)\) and \(\dot{p} = \mathcal{V}[v^v](t,p), P(0) = P\) respectively.

Using that and condition (II) for \(\mathcal{V}\) we get an estimate of \(\lambda(t)\):

\[
\lambda(t) = \int_{\mathbb{R}^6} \|T_{t,o}[\mu^v]P - T_{t,o}[v^v]P\| d\mu_0 \\
= \int_{\mathbb{R}^6} \int_{0}^{t} \mathcal{V}[\mu^v](\tau, T_{t,o}[\mu^v]P) d\tau - \mathcal{V}[v^v](\tau, T_{t,o}[v^v]P) d\tau \| d\mu_0 \\
\leq \int_{\mathbb{R}^6} \int_{0}^{t} \mathcal{V}[\mu^v](\tau, T_{t,o}[\mu^v]P) - \mathcal{V}[v^v](\tau, T_{t,o}[v^v]P) d\tau \| d\mu_0 + \\
+ \int_{\mathbb{R}^6} \int_{0}^{t} \mathcal{V}[v^v](\tau, T_{t,o}[v^v]P) - \mathcal{V}[v^v](\tau, T_{t,o}[v^v]P) d\tau \| d\mu_0 \\
\leq \int_{\mathbb{R}^6} \left( \int_{0}^{t} \| \mathcal{V}[\mu^v] - \mathcal{V}[v^v] \| d\tau \right) d\mu_0 + \int_{\mathbb{R}^6} \left( \int_{0}^{t} \| d\tau \right) d\mu_0 = (\text{Fubini})
\]

\[
= \int_{0}^{t} \int_{\mathbb{R}^6} \mathcal{V}[\mu^v](\tau, T_{t,o}[\mu^v]P) - \mathcal{V}[v^v](\tau, T_{t,o}[v^v]P) d\mu_0 d\tau + \\
+ \int_{0}^{t} \int_{\mathbb{R}^6} \mathcal{V}[\mu^v](\tau, T_{t,o}[\mu^v]P) - \mathcal{V}[v^v](\tau, T_{t,o}[v^v]P) d\tau d\mu_0 \\
+ \int_{0}^{t} \int_{\mathbb{R}^6} \mathcal{V}[\mu^v](\tau, T_{t,o}[\mu^v]P) - \mathcal{V}[v^v](\tau, T_{t,o}[v^v]P) d\tau d\mu_0 + \\
+ \int_{0}^{t} \int_{\mathbb{R}^6} \mathcal{V}[\mu^v](\tau, Q) - \mathcal{V}[v^v](\tau, Q) d\mu_0 d\tau + \\
+ \int_{0}^{t} \int_{\mathbb{R}^6} \mathcal{V}[\mu^v](\tau, T_{t,o}[\mu^v]P) - \mathcal{V}[v^v](\tau, T_{t,o}[v^v]P) d\mu_0 d\tau = (\text{II})
\]
\[ \lambda(t) \leq K \int_0^t \rho_1(\mu_\tau, \nu_\tau) d\tau + L \int_0^t \lambda(\tau) d\tau. \]

So we have

\[ \lambda(t) \leq K \int_0^t \rho_1(\mu_\tau, \nu_\tau) d\tau + L \int_0^t \lambda(\tau) d\tau \]

and

the well-known lemma of Gronwall provides

\[ \lambda(t) \leq K e^{Lt} \int_0^t \rho_1(\mu_\tau, \nu_\tau) e^{-Lt} d\tau. \]

The second term in the estimation for \( \rho_1(\mu_t, \nu_t) \) is more simple:

\[ \rho_1(\mu_t, \nu_t) \leq e^{Lt} \rho_1(\mu_0, \nu_0) + Ke^{Lt} \int_0^t \rho_1(\mu_\tau, \nu_\tau) e^{-Lt} d\tau. \]

Since \( T_0, t[\nu_\cdot] \) is Lipschitz continuous with constant \( e^{Lt} \),

\[ e^{-Lt}(\psi \circ T_0, t[\nu_\cdot]) \] is in \( D \) and we therefore get as a bound for the second term \( e^{-Lt} \rho_1(\mu_0, \nu_0). \)

Putting things together we have

\[ \rho_1(\mu_t, \nu_t) \leq e^{Lt} \rho_1(\mu_0, \nu_0) + Ke^{Lt} \int_0^t \rho_1(\mu_\tau, \nu_\tau) e^{-Lt} d\tau. \]

Applying Gronwall's lemma again, we get

\[ \rho_1(\mu_t, \nu_t) \leq e^{(K+L)t} \rho_1(\mu_0, \nu_0). \]

So, if \( \psi = \delta \) tends to \( \mu_0 \), \( \nu_t = \delta_N(t) \) tends to \( \nu_t \), which is the statement of the theorem.

Remarks:

1. One recognizes, that the solution of (9) depends even in a Lipschitz continuous way with Lipschitz constant \( e^{(K+L)t} \) on the initial data \( \mu_0 \). But one also can realize that the boundedness and the Lipschitz continuity of \( G \) is essential: Since \( K = 2LB \), both properties expressed by \( B \) and \( L \) are used.

2. Theorem 1 covers by far more than the special situation given by the Vlasov equation. Especially \( V \) may depend in a rather general way on \( \mu_0 \), whereas in the Vlasov case it depends
linearly on \( f(t, \cdot) \).

3. The crucial assumption is condition (II). There the integration with respect to \( \nu_t \) may be substituted by the integration with respect to \( \delta_{\omega_N(t)} \).
2. Existence and uniqueness for the modified Boltzmann equation

So far, we have assumed the existence of at least a measure theoretic solution of the modified Vlasov equation (2). It is now easy to establish existence and uniqueness in using the theory we have developed in lecture 1.

Theorem 2: If \( G \) is bounded and globally Lipschitz, then for any \( \hat{f} \in L^1 \) the modified Vlasov equation (2) has a global unique solution, which is a weak solution in the sense defined in (11). The solution is classical, if \( \hat{f} \) and \( G \) are in addition continuously differentiable.

Again we prove a more general statement: If \( V \) fullfills conditions (I) and (II), given in lecture 1, then the measure theoretic equation (9) has a unique weakly continuous solution \( \mu_* \) in any interval \([0,T]\).

Theorem 2 follows from that statement, since \( V \) given by (7) fullfills conditions (I) and (II) and, due to the lemma, a solution of (9) with absolutely continuous \( \dot{\mu} \) gives a weak solution of (2).

Proof: In \( M \) we defined the metric \( \rho_1 \); it induces a metric in \( C_M \), the set of all weakly continuous functions \( t \to \mu_t \in M, t \in [0,T] \), where \( T \) is arbitrary, but fixed:

\[
d_\alpha(\mu, \nu) := \sup_{t \in [0,T]} \rho_1(\mu_t, \nu_t)e^{-at}.
\]

Here \( a > 0 \) may be chosen freely. Since \( (M, \rho_1) \) is a complete metric space (Kellerer), the same is true for \( (C_M, d_\alpha) \).

We want to solve the equation (9)

\[
\mu_t = \mu_o \circ T_{0,t}[\mu_*].
\]

To this end, we introduce the operator

\[
(A_{\mu})(t) := \mu_o \circ T_{0,t}[\mu_*], t \in [0,T].
\]

Here we have to prove, that \( A_{\mu} \in C_M \), i.e. that

\[
t \to A_{\mu}(t), t \in [0,T]
\]

is weakly continuous. But this is an immediate consequence of a
well known theorem, which says, that \( \mu_0 \circ T_{O,t}[u] \) is weakly continuous, if

\[
\mu_0([P = \mathbb{R}^6 | T_{O,t} \text{ is continuous at } (t,P)]) = 1.
\]

Since \( T_{O,t} \), considered as a function of \((t,P)\) is everywhere continuous (it is a solution of an ordinary differential equation system), \( \mu_0 \circ T_{O,t}[u] \) is weakly continuous for each \( \mu_0 \).

Now we simply have to show, that \( A \) is for suitable \( \alpha \) a contractive mapping in \( (C_M, d_\alpha) \).

First we get for arbitrary \( u, v \in C_M \)

\[
\rho_1(Au, Av)(t) = \rho_1(\mu_0 \circ T_{O,t}^t[u], \mu_0 \circ T_{O,t}^t[v])
\]

\[
\leq Ke^{-Lt} \int_0^t \rho_1(u_\tau, v_\tau) e^{-L_\tau} d\tau
\]

as we already saw in the proof of theorem 1.

Therefore

\[
d_\alpha(Au, Av) \leq K \sup_{t \in [0, T]} e^{(L-\alpha)t} \int_0^t \rho_1(u_\tau, v_\tau) e^{-L_\tau} d\tau
\]

\[
\leq K \sup_{t \in [0, T]} e^{(L-\alpha)t} \int_0^t d_\alpha(u_\tau, v_\tau) e^{-(L-\alpha)\tau} d\tau
\]

\[
= \frac{K}{\alpha - L} d_\alpha(u, v) \quad \text{for } \alpha > L
\]

Choosing \( \alpha = K + L + \delta \) for \( \delta > 0 \) yields

\[
d_\alpha(Au, Av) \leq \frac{1}{1 + \frac{\delta}{K}} d_\alpha(u, v)
\]

so \( A \) is a contractive operator and from the Banach fixpoint theorem the statement of the theorem follows.

Remark: The proof of theorem 2 is of Picard-Lindelöf type. One may also make a proof of Peano type: For \( \mu = \frac{\delta}{\omega_N} \) the solution \( \omega_N(t) \) of (9) exists. One can show by using Prohorov's theorem on compactness in \( M \), that \( \{\omega_N(t), n \in N\} \) is relatively compact in \( M \) for each \( t \).

Therefore for each \( t \) a sequence \( (n_j(t)) \), \( j \in N \) exists, such that \( \omega_{n_j}(t) \) converges to a measure \( \mu_t \). Now one has to show, that
n_j can be chosen independently of t, so that
\[ \delta_{\omega_{n_j}(t)} \rightarrow \mu_t \quad \text{for all } t \in [0,T]. \]
That \( \mu_t \) gives a solution of (9). The advantage of that procedure is not very big; one can weaken a little bit condition (I). But we need that kind of arguments in order to prove the existence of a weak solution for the non-modified Vlasov equation.

Historical remarks: The first existence proof for the modified Vlasov equation was given by Batt in 1963, who also introduced the modification. He had stricter assumptions concerning \( f \). The theorems 1 and 2 given here were proved by me in 1975. Braun and Hepp in 1977 as well as Dobrushin in 1978 were not aware of these results and proved some slightly weaker results using the metric \( p_2 \).
3. Existence and uniqueness for the unmodified Vlasov equation

The research concerning existence and uniqueness for the unmodified Vlasov equation proceeded in two different directions:

(a) One looks for weak solutions, gets existence for dimension 3, but uniqueness is not proved up till now. Existence theorems for weak solutions have been shown by Arseneev and Illner and myself.

(b) One looks for classical solutions, for which uniqueness is easy to show. But one has to make some assumption on the initial data, which are restricting. So for \( \hat{f} \) depending only on two space and two velocity variables or for \( f \) being in a certain way symmetric, one gets existence. These results are mainly due to E. Horst (1980), but Batt did the first step in that direction; also Ukai, Okabe and Wollmann showed the existence of classical solutions for the "two-dimensional" case.

Since all the proofs of these theorems are rather long and technical, I just try to give the results and some impressions of the ideas lying behind.

In both cases the idea is initially the same: In order to solve (2) with initial condition \( f(0, \cdot) = \hat{f} \) and \( G \) given (1) one first solves the Vlasov equation with a modified \( G_\delta \) — we call that equation now (2\( _\delta \)) — and the same initial value \( \hat{f} \); the solution of that problem, which for any \( f_\in L^1 \) exists as theorem 2 shows, is denoted by \( f_\delta \). Letting \( \delta \) tend to 0, one hopes to get a solution of (2).

The difference of both cases lies in the kind of convergence one has to prove: Whereas in (a), where \( \hat{f} \) may be chosen arbitrarily in \( L^1 \), one only has to prove weak convergence of \( f_\delta \), in case (b), where \( f \) has to be continuously differentiable one has to show uniform convergence.

But there is another thing in common for both cases: One has to show, that, if

\[
F_0 = \int_{\mathbb{R}^6} ||v||^2 \hat{f}(x,v) \, dx \, dv < \infty
\]
then there exists a constant $C$, not depending on $t$ and $\delta$, so that the kinetic energy of the gas fulfills the estimate

$$E_\delta(t) := \int_{\mathbb{R}^6} \|v\|^2 f_\delta(t,x,v) \, dx \, dv \leq C.$$

(16) is proved by showing that energy conservation holds: Let $U_\delta(x,y)$ be the potential of $G_\delta$, i.e.

$$G_\delta(x,y) = 4\pi \int_{\mathbb{R}^3} \frac{1}{|x-z|} \omega_\delta(z-y) \, dz.$$

(for example $U_\delta(x-y) := -\frac{1}{|x-y|} \omega_\delta(x-y)$ for one kind of mollifying or $U_\delta(x-y) = \frac{-\frac{1}{|x-y|^2}}{\sqrt{|x-y|^2 + \delta}}$ for the other)

and define the potential energy of the solution $f_\delta$ by

$$V_\delta(t) := \int_{\mathbb{R}^6} \int_{\mathbb{R}^3} U_\delta(x-y) f_\delta(t,y,v) \, dy \, dv \, dx \, dv;$$

(17) then

$$E_\delta(t) + V_\delta(t) = E_0 + V_\delta(0).$$

(18) holds for all $t > 0$.

(18) is rather easy to prove by using (9).

(16) follows immediately from (18) in the plasmaphysical case, where $\gamma < 0$; $U_\delta(x-y)$ is then nonnegative, so this is true for $V_\delta(t)$ and

$$E_\delta(t) = E_0 + V_\delta(t) \geq E_0 + V_\delta(0),$$

where $V_\delta(0)$ may be bounded uniformly with respect to $\delta$.

(16) is harder to prove in the stellardynamic case, where $\gamma > 0$. But nevertheless it is true as was shown by Horst in using some Sobolev inequalities.

Let us now present the existence theorems:
Theorem 3: If \( \mathcal{L}^1 \) has the following properties:

(i) There exists a \( M \) such that \( 0 \leq f(x) \leq M \) a.e. in \( \mathbb{R}^6 \)

(ii) \( \int_{\mathbb{R}^6} ||P||^2 f(P) dP < \infty \)

(iii) \( \rho: x \mapsto \int_{\mathbb{R}^6} \frac{\rho}{||P||^2} f(x,v) dv \) is essentially bounded.

then a weak solution \( f(t,\cdot) \) of the initial value problem for (2) exists.

Sketch of the proof:

1. step: Let \( \mu_\delta^t : t \mapsto \mu_\delta^t, t \in [0,T] \) the solution of (9) with mollified \( G_\delta \). Then one shows, that the set \( \{ \mu_\delta^t | t \in [0,T], \delta > 0 \} \) is uniformly tight in \( M \); that means: to every \( \epsilon > 0 \) there exists a \( R > 0 \), such that

\[
\mu_\delta^t(\mathbb{R}^6 \setminus K_R) < \epsilon \quad \text{for all } t \in [0,T], \delta > 0;
\]

where \( K_R := \{ P \in \mathbb{R}^6 | ||P|| \leq R \} \).

This is shown by considering

\[
h_\delta(t) := \int_{\mathbb{R}^6} ||x||^2 f_\delta(t,x,v) dx dv;
\]

using, that \( f_\delta \) is a solution of (9) and using (16) one gets

\[
0 \leq h_\delta(t) \leq C' \quad \text{independent on } \delta > 0 \text{ and } t \in [0,T].
\]

Now, for any \( R > 0 \)

\[
R^2 \mu_\delta^t(\mathbb{R}^6 \setminus K_R) = R^2 \int_{\mathbb{R}^6 \setminus K_R} f_\delta(t,P) dP \leq \int_{\mathbb{R}^6 \setminus K_R} ||P||^2 f_\delta(t,P) dP < \infty
\]

\[
\leq \int_{\mathbb{R}^6} ||P||^2 f_\delta(t,P) dP = h_\delta(t) + E_\delta(t) \leq C + C',
\]

again using (16); therefore \( \mu_\delta^t(\mathbb{R}^6 \setminus K_R) \) can be made smaller than an arbitrary \( \epsilon > 0 \) by choosing \( R \) large enough.

Now Prohorov's theorem shows, that for any countable dense subset \( T' \subset [0,T] \) there is a monotone sequence \( (\delta_n)_{n \in \mathbb{N}} \) such that

\[
\mu_\delta^t_n := \mu_\delta^t \rightarrow \mu_\delta^t \in M \quad \text{for } n \rightarrow \infty, \ t \in T'.
\]

We have next to show, that the convergence holds also for \( t \not\in T' \).
2. step: We show, that for any continuously differentiable \( \psi \) with compact support, the set of functions
\[
\phi_n(t) := \int_{\mathbb{R}^6} \psi \, d\mu^t, \quad t \in [0,T]
\]
is equicontinuous. This is a technical proof, using mainly the boundedness of \( f^t \) and therefore also of \( f^\delta \).

Now, since \( \phi_n \) converges pointwise on \( T' \) and forms an equicontinuous set, it converges uniformly on \([0,T]\). The limit has to be
\[
\lim_{n \to \infty} \phi_n(t) = \int_{\mathbb{R}^6} \psi \, d\mu^t
\]
with \( \mu^t \in M \) defined for all \( t \in [0,T] \). It follows immediately, that
\[
\mu^t_n \to \mu^t \quad \text{for} \quad t \in [0,T]
\]
and that \( \mu^t : t \to \mu^t \) is weakly continuous.

It is also easy to show, that \( \mu^t \) is absolutely continuous with a density \( f(t,\cdot) \) essentially bounded by \( M \).

3. step: What stays is a long but straightforward proof, that \( f(t,\cdot) \), constructed in step 2 is a weak solution of the initial value problem for (2). We will not go into details.

Remark: The existence proof sketched here is not constructive, since it uses a compactness argument and we are not able to show, that for \( \delta_n \in N \) the measures \( \mu^t_n \) converge to \( \mu^t \). This has two consequences:

(i) We are not able to prove uniqueness - we will even not make any conjecture on that problem.

(ii) Since it is not possible to show, that \( \nu_1(\mu^\delta_t, \mu^t) \) is small for small \( \delta \), we cannot prove, that the unmodified Vlasov equation is strictly derivable - even for the plasmaphysical case, where the discrete problem has a global solution. It might be true, that the equation is only stochastically derivable - a notion, which we will not define here, since it is more connected with the Boltzmann equation.
We now turn to the question of existence of classical solutions, i.e. to Horst's work. Here we will always assume that $\phi$ is continuously differentiable and has compact support.

As already mentioned there is up till now no existence theorem for the full 3-dimensional problem. Therefore we have to consider the following lower dimensional cases:

(A) The function $f$ in equation (2) depends only on 2 space and 2 velocity variables. Then equation (1) has to be changed into

$$G(x,y) = \gamma y \ln ||x-y|| = -\gamma \frac{x-y}{||x-y||^2}$$

(B) Let $H$ be the group of all orthogonal transformations $S$ of $\mathbb{R}^3$ with $\det S = 1$. A function $g : (x,y) \rightarrow \mathbb{R}, (x,v) \in \mathbb{R}^6$ is called to be spherically symmetric if $g(Sx,Sv) = g(x,v)$ for all $S \in H, (x,v) \in \mathbb{R}^6$.

Now it is easy to show, that if $\phi$ is spherically symmetric, a solution of the corresponding initial value problem for (2) is also spherically symmetric. So the question occurs, whether such a solution for a spherically symmetric initial condition exists.

(C) Let $Z$ be the group of orthogonal transformations $Z_\delta$ of $\mathbb{R}^3$, which are represented by matrices of the form

$$Z_\delta := \begin{bmatrix} \cos \theta & \sin \theta & 0 \\ -\sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{bmatrix}, \ 0 \leq \theta \leq 2\pi$$

A function $g$ is called rotationally symmetric, if $g(Z_\delta x,Z_\delta v) = g(x,v)$ for all $(x,v) \in \mathbb{R}^6, Z_\delta \in Z$. Again for $\phi$ rotationally symmetric the corresponding solution $f(t,\cdot)$ of (2) is also rotationally symmetric and one may ask for the existence of such solutions. This problem may be considered as a 5-dimensional version of the original 6-dimensional problem. The special part of the z-axis given by the form of $Z_\delta$ is not essential.

**Theorem 4:** In each case (A), (B) or (C) there exists a global classical solution, which is unique.
Sketch of the proof: One again starts with the solutions \( f_\delta \) of the modified problem. The main tool is the following lemma, which was in a similar form first proved by Batt.

**Lemma:** There exists a unique classical solution of the initial value problem for (2) in \([0, T]\), if and only if

\[
\sup_{x \in \mathbb{R}^3} \int_{\mathbb{R}^3} f_\delta(t,x,v)dv \mid t \in [0,T], \quad x \in \mathbb{R}^3, \delta > 0 < \infty
\]

The proof of that lemma is rather long but purely technical. One gets an estimate of the form

\[
\|T_{t,t_0} [v_\delta^j]P - T_{t,t_0} [v_\delta^j]P\| \leq C \left| \frac{1}{\delta^4} - \frac{1}{\delta_4^4} \right|
\]

\( C \) depending only on the length \( T \) of the time interval. Therefore \( T_{t,t_0} [v_\delta^j]P \) converges uniformly with respect to \( t, t_0 \in [0, T] \), \( P \in \mathbb{R}^6 \) for \( \delta \) tending to zero to a mapping \( T_{t,t_0}(P) \).

Defining \( f(t,P) := f(T_{t_0,t} P) \) one gets a solution of (2).

Since we have now full convergence for \( \delta \) tending to zero (in contrast to the situation with weak solutions, where we only know the existence of a sequence \((\delta_j)_{j \in \mathbb{N}}\) for which \( v_\delta^j \) and \( T_{t_0,t} [v_\delta^j] \)

converges), uniqueness also follows immediately.

For the rest one needs again (16), i.e. the fact, that the kinetic energy of \( f_\delta \) is bounded uniformly with respect to \( \delta \). Applying Hölder's inequality, one gets for

\[
\rho_\delta(t,x) = \int_{\mathbb{R}^3} f_\delta(t,x,v)dv
\]

that

\[
\|\rho_\delta(t, \cdot)\|_5 \leq K \|f\|_5^2 \cdot E_\delta^3 \leq C_1.
\]

But in order to use the lemma, we need a uniform bound for \( \|\rho_\delta\|_\infty \).

Therefore one proceeds as follows: We estimate

\[
K_\delta(t,x) := \int_{\mathbb{R}^3} G_\delta(x-y)f_\delta(t,y,v)dydv = \int_{\mathbb{R}^3} G_\delta(x-y)\rho_\delta(t,y)dy
\]

by Sobolev's inequality to get
\[(21) \quad ||X_\delta(t, \cdot)||_\infty \leq C_2 \rho_\delta^{\frac{4}{9}} \]

But if we are aware of the symmetry of \(f_\delta\), for example the spherical symmetry, one gets better estimates:

\[(22) \quad |K_\delta(t, x)| \leq C_3 \frac{1}{\sqrt{x_1^2 + x_2^2}} \rho_\delta^{\frac{1}{6}}.\]

There the symmetry comes in! Now recall, that \(T_{t, 0}|_{\mu^\delta}\) is a solution of the system
\[
\begin{align*}
\dot{x} &= v \\
\dot{v} &= K_\delta(t, x).
\end{align*}
\]

Therefore estimates for \(F_\delta\) give estimates for \(T_{t, 0}|_{\mu^\delta}\). Considering only the last three components of \(T_{t, 0}|_{\mu^\delta}\), which correspond to the velocities and estimating
\[G_\delta^j := \sup \{|(T_{t, 0}|_{\mu^\delta})_P|_{3+j} - P_{3+j}| \mid P \in \mathbb{R}^6, t \in [0, T]\}\]

one gets, that if \(|K_\delta(t, x)| \leq g(x_j)|\) for some \(j \in \{1, 2, 3\}\) and \(g \in L^p\), then
\[G_\delta^j \leq C_4 \|g\|_{\frac{p}{p+1}}.\]

\(C_4\) only depending on \(p\) and \(T\).

Now using (21) for \(G_\delta^3\) gives
\[G_\delta^3 \leq C_5 \|\rho_\delta\|^{\frac{4}{9}}.\]

Using (22) for \(G_\delta^1\) and \(G_\delta^2\) gives
\[G_\delta^1, G_\delta^2 \leq C_6 \|\rho_\delta\|^{\frac{11}{45}}.\]

The exponents look strange but are important. Since
\[\rho_\delta(t, x) = \int_\mathbb{R}^3 f(T_{t, 0}|_{\mu^\delta})_P dv\]

these estimates for \(G_\delta^j\) can be used again to give estimates for \(\rho_\delta\).

One gets
\[\|\rho_\delta\|_\infty \approx (G_1^\delta + \epsilon)(G_2^\delta + \epsilon)(G_3^\delta + \epsilon)\]

\((\alpha, \beta \text{ independent of } \delta)\) and therefore
(23) \[ \| \rho_\delta \|_\infty \leq O(\| \rho_\delta \|_{15}^{14}) \] uniformly in \( \delta \).

Note, that \( \frac{14}{15} \approx \frac{4}{9} + \frac{11}{45} + \frac{11}{45} \) - and note that without symmetry we would have instead of \( \frac{14}{15} \) a number larger than one: \( 3 \cdot \frac{4}{9} = \frac{4}{3} \).

You see, that (23) cannot be true, if \( \| \rho_\delta \|_\infty \) is not bounded. This proves (19) and therefore theorem 4.

**Remark:** I gave some of the most important estimates in Horst's work in order to show you how tough the stuff is. The methods end up with an estimate of the type

\[ \| \rho_\delta \|_\infty = O(\| \rho_\delta \|_\infty^k) \]

and if \( k < 1 \), then we are through. In the twodimensional case we have just \( k = 2 \cdot \frac{4}{9} < 1 \) without symmetries. But for three dimensions this method fails.

It is hard to guess whether there is a unique classical solution of (2) in 3 dimensions. The situation is similar to the situation in the field of Navier-Stokes equations:

In 3 dimensions one has existence but not uniqueness for weak solutions, uniqueness but not existence for classical solutions; in lower dimensions existence and uniqueness of classical solutions.

What about higher dimensions? Nothing is known for Navier-Stokes and nothing is known for Vlasov in the plasmaphysical case. But here is the only essential difference between \( \gamma = +1 \) and \( \gamma = -1 \) - Horst has shown, that there is no global solution in 4 dimensions for the stellardynamic case. Since that result is at least mathematically surprising and since the proof is simple, I state it as

**Theorem 5:** In 4 dimensions for \( \gamma > 0 \) there are initial values \( \phi \) (positive, continuously differentiable with compact support), such that the corresponding initial value problem for (I) has no global solution.
Remark: 4 dimensions mean 4 space and 4 velocity variables. G has to be then
\[ G(x, y) = -\gamma \frac{x - y}{||x - y||^4}, \quad x, y \in \mathbb{R}^4. \]

Proof: We consider the moment of inertia for a solution of (2) (for times \( t \), when it exists).

\[ m_i(t) := \int ||x||^2 f(t, x, v) dx dv \]

With \( V \) defined like in (17) and with \( f \) instead of \( f_\delta \) and
\[ U(x-y) = \frac{\gamma}{2} \frac{1}{||x-y||^2} \]
instead of \( U_\delta \) (\( V \) is the potential energy) one gets by straightforward calculation, that \( m_i \) is twice continuously differentiable and
\[ m_i''(t) = 2(E(t) + V(t)) = 2(E(0) + V(0)) \]
(here the 3 dimension comes in; in 3 dimensions it would just be \( m_i''(t) = 2E(t) + V(t) \) and we could not use the energy conservation).

Now choose a \( \delta \) such that \( E(0) + V(0) < 0 \). This is possible only in the stellardynamic case, where \( \gamma > 0 \), since \( E(0) \) is positive but linear in \( \delta \) and \( V(0) \) is negative but quadratic in \( \delta \).
Therefore \( m_i''(t) \) is a negative constant. \( m_i \) itself is positive, since \( \delta \) and therefore \( f \) is positive. This is possible only in certain finite time intervals. So the solution can only exist in a finite time interval (which depends only on \( f \)). That was to be shown.
4. The plasmaphysical case with selfconsistent magnetic field

If the particles considered are electrons, they do not only interact by means of the electric field but also by the magnetic field generated by themselves. Therefore instead of looking only at the electric field

$$E(t, x) = \int G(x, y)f(t, y, v)dydv = \int G(x, y)\rho(t, y)dy$$

in (2), which is a solution of $\text{div} E = -4\pi \gamma \rho$, we have to take into account the full Maxwell equations. In order to be in accordance with a familiar form of these equations, we slightly change the notation.

Instead of (1), (2) the system of equations we have to consider now is the following system for the function $f$, the electric field $E$ and the magnetic field $B$:

\begin{align}
(2') & \quad \frac{\partial f}{\partial t} + \langle v, \text{grad}_x f \rangle - \langle E[f] + \frac{1}{c} v \times B[f], \text{grad}_v f \rangle = 0 \\
(1a) & \quad \text{div } E = 4\pi (n_e + n_i) \\
(1b) & \quad \text{div } B = 0 \\
(1c) & \quad \text{rot } E = -\frac{1}{c} \frac{\partial B}{\partial t} \\
(1d) & \quad \text{rot } B = \frac{1}{c} \frac{\partial E}{\partial t} + \frac{4\pi}{c} j
\end{align}

where

\begin{align}
(25) & \quad n_e(t, x) := -\int f(t, x, v)dv, \quad j(t, x) := -\int vf(t, x, v)dv \\
\end{align}

and $n_i = n_i(x)$ is a given spatial density of a fixed ion background.

Remarks:

(a) If $B = 0$ and $n_i = 0$, then (2') is essentially (2), provided we add to (1a) the boundary condition that $E$ has to vanish at infinity. Then (1a) has the solution

$$E(t, x) = \int G(x, y)n_e(t, y)dy$$

with $\gamma = -1$.

(b) In (2') we write $E|f|$ and $B|f|$ in order to make clear that the fields depend on $f$: $n_e$ and $j$ are moments of $f$, therefore a solu-
tion of the system (1a) - (1d) depends on f.

(c) We introduced the function \( n_1 \) representing the spatial density of a ion gas, while \( f \) is the \( u \)-space density for the electrons. We assume that the ions form a fixed background. Otherwise we would have to consider two distribution functions \( f_e \) and \( f_1 \) and two equations of the form (2'), which differ only by a constant and a sign in front of the third term. This would not cause principal difficulties but increase the formal complexity of the system.

We mention that the introduction of a \( n_1 \) and even of an external magnetic field, which does not depend on \( f \), into equations (1) - (2) of the preceding lectures would not have generated essential troubles and could have been handled easily.

In order not to get lost in the complexity of the problem we are looking for the simplest geometry in which the typical features of the problem are present. If \( f \) would depend only on one space and one velocity variable no magnetic field would occur. Therefore we look for solutions which depend only on one space and on two velocity variables:

\[
f(t, \cdot) : (x_1, v_1, v_2) \mapsto f(t, x_1, v_1, v_2) \geq 0 \text{ for all } p := (x_1, v_1, v_2) \in \mathbb{R}^3.
\]

For such a function \( n_0 \) and \( j \) defined by (25) do not exist. Therefore we change these definitions into

\[
(25') \quad n_0(t, x_1) = - \int_{\mathbb{R}^2} f(t, x_1, v) dv, \quad j(t, x) = - \int_{\mathbb{R}^2} v f(t, x_1, v) dv
\]

with \( v = (v_1, v_2) \).

Furthermore, we add some boundary conditions for \( E \) and \( B \), which also will depend only on \( x_1 \):

\[
(26a) \quad \lim_{x_1 \to -\infty} E_1(t, x_1) = \lim_{x_1 \to +\infty} E_1(t, x_1), \quad t \in [0, T]
\]

\[
(26b) \quad E_2(0, x_1) = E_2(x_1), \quad E_3(0, x_1) = 0 \quad \text{for all } x_1 \in \mathbb{R}
\]

\[
(26c) \quad B_1(0, x_1) = B_2(0, x_1) = 0, \quad B_3(0, x_1) = B_3(x_1) \quad \text{for all } x_1 \in \mathbb{R}.
\]
It follows that \( B_1(t,x_1) = B_2(t,x_1) = E_3(t,x_1) = 0 \) everywhere and instead of (1a) - (1d) the simpler system

\[
(1a') \quad \frac{\partial E_1}{\partial x_1} = 4\pi (n_e + n_i)
\]

\[
(1c') \quad \frac{\partial E_2}{\partial x_1} + \frac{1}{c} \frac{\partial B_3}{\partial t} = 0
\]

\[
(1d') \quad \frac{\partial E_1}{\partial t} = -4\pi j_1, \quad \frac{\partial E_2}{\partial t} + c \frac{\partial B_3}{\partial x_1} = -4\pi j_2.
\]

remains to be considered.

(2') becomes

\[
(2'') \quad \frac{\partial f}{\partial t} + v_1 \frac{\partial f}{\partial x_1} - (E_1[f] + \frac{1}{c} v_2 E_3[f]) \frac{\partial f}{\partial v_1} - (E_2[f] - \frac{1}{c} v_1 E_3[f]) \frac{\partial f}{\partial v_2} = 0
\]

The initial value problem for the system (2'), (1a'), (1c') and (1d') is unmodified in the sense of lecture 1 but lower dimensional. I suggest that it has a unique classical solution. But this is not yet proved. Only for a "mollified" problem existence and uniqueness is assured and I will sketch that result (see [25]).

Instead of defining \( n_e \) and \( j \) as in (25') we use a smoothed \( f_\delta \) instead of \( f \) and define

\[
(25'') \quad n_e^\delta(t,x_1) = - \int_{\mathbb{R}^3} \omega \delta(x_1-\xi) \ f(t,\xi,v) \ dv \ dt
\]

\[
j^\delta(t,x_1) = - \int_{\mathbb{R}^3} v \omega \delta(x_1-\xi) \ f(t,\xi,y) \ dv \ dt
\]

Now our problem is completely stated by the equations (1a'), (1c'), (1d'), (2'') and (25''), where into the equations (1') \( n_e^\delta, j^\delta \) must be inserted instead of \( n_e, j \). We have to add the initial and boundary conditions (26) for \( B, E \) and \( f \).

We first solve the equations (1a'), (1c') and (1d') for given \( f(t,\cdot) \).

Let \( \mu_\ell \) be again the measure with the density \( f(t,\cdot) \). We have to be a little bit more careful, as \( \mu_\ell \) has to be such that
\[
    j^\delta(t, x_1) = \int \mathbb{R}^3 \nu_\delta(x_1 - \zeta) \, d\mu_t(\zeta, \nu)
\]
exists. But the function \((\zeta, \nu) \mapsto \nu_\delta(x_1 - \zeta)\), \(x_1\) fixed, is not bounded. That causes some trouble, in contrast to the situation of lecture 1.

We will therefore assume, that the supports of \(\mu_t\), \(t \in [0, T]\) are uniformly bounded with respect to \(t\); i.e. there exists a ball 
\[
    \kappa_R = \{P \in \mathbb{R}^3 / \|P\| \leq R\}
\]
such that
\[
    \text{supp } \mu_t \subset \kappa_R \quad \text{for } t \in [0, T].
\]

Now (1a') with the boundary condition (26a) has the solution
\[
    E_1(t, x_1) = 2\pi \int_{-\infty}^{+\infty} \text{sign}(x_1 - y) \left[ n_e^\delta(t, y) + n_1(y) \right] dy
\]
\[
    = 2\pi \int_{\mathbb{R}^3} \left( \int_{-\infty}^{+\infty} \text{sign}(x_1 - y) \omega_\delta(y - z) \, dy \right) d\mu_t(z, \nu)
\]
\[
    + 2\pi \int_{-\infty}^{+\infty} \text{sign}(x_1 - y) n_1(y) \, dy.
\]

It is easy to check, that \(E_1\) is continuous and bounded in \([0, T] \times \mathbb{R}\), is globally Lipschitz continuous with respect to \(x\) with a Lipschitz constant independent of \(t\) and \(\nu\). Furthermore, by doing the same small calculations as in lecture 1 one gets
\[
    |E_1[\mu, \nu](t, x) - E_1[\nu, \nu](t, x)| \leq \kappa_1 \rho(\mu_t, \nu_t).
\]

For arbitrary \(\mu\), the function \(E_1\) given by (27) will in general not satisfy the first equation in (1d'). We forget that equation for a moment; it will turn out at the end that, if \(\mu\) is a solution of our problem, this equation is automatically satisfied.

Now we have to consider the equations
\[
    \frac{\partial E_2}{\partial x_1} + \frac{1}{c} \frac{\partial B_3}{\partial t} = 0, \quad \frac{\partial E_2}{\partial t} + c \frac{\partial B_3}{\partial x_1} = -4\pi j^\delta_2
\]
with the initial condition \(E_2(0, x_1) = E_2(x_1), \ B_3(0, x_1) = B_3(x_1)\).

To solve them we look for a function \(A: [0, T] \times \mathbb{R} \rightarrow \mathbb{R}\), so that
\[ (28) \quad B_3 = \frac{\partial A}{\partial x_1}, \quad E_2 = -\frac{1}{c} \frac{\partial A}{\partial t} \]

is a solution. Inserting this "Ansatz" into the equations for \( E_2, B_3 \) we get

\[ (29) \quad \frac{\partial^2 A}{\partial x_1^2} - \frac{1}{c^2} \frac{\partial^2 A}{\partial t^2} = -\frac{4\pi}{c} \delta(t - t') \]

i.e. the inhomogenous wave equation. Its solution is

\[ A(t, x_1) = -\frac{4\pi}{c} \int C \frac{x_1 + c(t - t')}{x_1 - c(t - t')} j_2(t, y) dy \]

\[ A(t, x_1) = \left( \frac{x_1 + ct}{x_1 - ct} \right)^{1/2} \left( \frac{x_1 - ct}{x_1 + ct} \right)^{1/2} B_3(y) dy \]

\[ (30) \quad A(t, x_1) = \left( \frac{x_1 + ct}{x_1 - ct} \right)^{1/2} \left( \frac{x_1 - ct}{x_1 + ct} \right)^{1/2} B_3(y) dy \]

\[ E_2 \text{ and } B_3 \text{ given by } (28), (30) \text{ satisfy similar conditions as } E_1; \]

They are globally Lipschitz continuous uniformly with respect to \( t \) and \( x_1 \) and there are constants \( K_2, K_3, M_2, M_3 \), such that

\[ (31) \quad |E_2[\mu_1](t, x_1) - E_2[\nu_1](t, x_1)| \leq K_2 \rho(\mu_1, \nu_1) + M_2 \int_{\mathbb{R}} \rho(\mu_1, \nu_1) dt \]

\[ |B_3[\mu_1](t, x_1) - B_3[\nu_1](t, x_1)| \leq K_3 \rho(\mu_1, \nu_1) + M_3 \int_{\mathbb{R}} \rho(\mu_1, \nu_1) dt \]

However, these constants \( K_2, K_3, M_2, M_3 \) depend on the bound of the supports of \( \mu_t \), i.e. on \( \mathbb{R} \).

The vectorfield \( V[\mu_1] \), defined by

\[ V[\mu_1](t, x_1, \nu) := \left\{ \begin{array}{c} V_1 \\ -E_1[\mu_1] - \frac{1}{c} \nu_2 B_3[\mu_1] \\ -E_2[\mu_1] + \frac{1}{c} \nu_1 B_3[\mu_1] \end{array} \right. \]

satisfies condition (I) of lecture 1; condition (II) has to be generalized to

\[ (11') \quad \int_{\mathbb{R}} \| V[\mu_1](t, \nu) - V[\nu_1](t, \nu) \| d\mu_t(\nu) \]

\[ K_P(\mu_1, \nu_1) + M \int_{\mathbb{R}} \rho(\mu_1, \nu_1) dt \]
There $k = 3$; the additional term $M \int_0^T \mu_t(t, x_1, x_2) \, dt$ causes no trouble in any proof. What is really unpleasant is the fact, that (I) and (II') are only satisfied, if $\mu_t, x_1, x_2, t \in [0, T]$ have uniformly bounded support. We need an a priori estimate: If $\mu_t$ is in $[C, T]$ a solution of the initial value problem with $\hat{\mu}$ having bounded support, then $\mu_t, t \in [0, T]$ has uniformly bounded support.

In order to prove this we consider again the kinetic energy

$$(16') \quad W(t) := \int_{\mathbb{R}^3} \|v\|^2 \, d\mu_t(x_1, v)$$

(We use $W$ instead of $E$ in order to avoid confusion with the electric field). Using the fact, that $\mu_t$ is a solution of (2n') we get

$$W(t) = -2 \int_{\mathbb{R}^3} (v_1 E_1(t, x_1) + v_2 E_2(t, x_1)) \, d\mu_t(x_1, v).$$

From (27), (28) and (30), we get

$$W(t) \leq W(0) + 2\alpha (t + \int_0^t W(\tau) \, d\tau) + 4\pi c_\delta t.$$  

$$(\text{with } \alpha = c + 4\pi) \text{ and finally}$$

$$0 \leq W(t) \leq C_1 + C_2 \int_0^t W(\tau) \, d\tau, \text{ where } C_1, C_2 \text{ are dependent on } W(0), T \text{ and } \delta.$$  

An application of Gronwall's lemma yields $0 \leq W(t) \leq A$ for $t \in [C, T]$, where $A$ depends only on $W(0), \delta$ and $T$.

As $\int_{\mathbb{R}^3} |v_1| \, d\mu_t(x_1, v) \leq 1 + W(t)$, $i = 1, 2$, we get a uniform bound for these integrals and therefore also for $E_1, E_2$ and $B_3$. Hence

$$\|V[\mu_t](t, P)\| \leq L_1 + L_2 \|P\| \text{ for } t \in [0, T], P \in \mathbb{R}^3$$

with constants depending only on $\mu_t, \delta$ and $T$. It follows that

$$\|T_{t, 0}[\mu_t]Q\| \leq (\|Q\| + L_1 T) e^{L_2 T}, \quad t \in [0, T], Q \in \mathbb{R}^3$$

Choosing $R := (r + L_1 T) e^{L_2 T}$, we see that for $Q \in \text{supp } \mu_t$ the point
$T_{t_0}[\mu.]Q$ is contained in $\kappa_R$ and therefore

$$\text{supp } \mu_t = \text{supp}(\mu_0 \circ T_{t_0}[\mu.]) \subset \kappa_R.$$ 

This gives the desired a priori estimate.

The remaining part of an uniqueness and existence proof is simple: One first shows a local (with respect to time) theorem by one of the standard methods and continues the solution by using the a priori estimate. The details can be found in [25]. This result is

**Theorem 6:** For $f \in L^1(\mathbb{R}^3)$ with compact support the corresponding initial value problem given by (2''), (1a'), (1c'), (1d'), (25'') together with the initial-boundary condition (26) has in any intervall $[0,T]$ a unique (weak) solution. The solution is classical if the initial data $\phi, \tilde{E}_2$ and $\tilde{B}_3$ are continuously differentiable.

**Remark:**

The following questions arise but are not answered till now.

1. Could a similar theorem be proved without reducing the dimension of the problem, i.e. for the sixdimensional "mollified" case? Since no essential use of the dimension is made and the advantage consists only in getting solutions of the Maxwell equations, which are easy to handle, there should be a good chance for a positive answer.

2. Is it possible to take the limit $\delta \to 0$ to get solutions for the unmodified equations? It should be by far easier to get existence but not uniqueness of weak solutions. (Inspite of not having shown, that a $\delta$-independent bound for the kinetic energy $W$ exists) than to prove something about classical solutions.

Theorem 6 might be considered only as a first step in solving a problem, which is of high interest for applications in plasma physics.
5. **Numerical Methods, in particular Simulation Procedures**

There exist a lot of numerical methods in order to solve the Vlasov equation approximately. Difference schemes, Fourier expansions with respect to x, Hermite polynomials are used as well as the so-called waterbag model, which uses the fact that if $\tilde{f}$ is a stepfunction, then the solution $f(t, \cdot)$ is of the same kind. As far as I know, for none of these methods convergence is proved. Besides these methods plasmaphysicists very often use so-called simulation methods, especially the "particle-in-cell"-method (PIC), developed for the Vlasov equation by R. Morse. Since the convergence of this method can be proved by the methods developed in lecture 1, we will describe it in more details.

The main idea of a simulation in the kinetic theory is simply as follows: A real gas consists of say $10^{23}$ particles. The Vlasov equation describes a gas of infinitely many particles (in the sense given in lecture 1). Let's try to create a gas of about $10^4$ particles, whose motion is governed by the rules of classical mechanics such that this gas behaves "as similar as possible" to the infinite particle system.

In order to make this more precise, we reformulate the idea:

Let $N$ be the number of particles in a real system, $\delta^0_N$ the initial state and $\bar{\rho} = \int \delta^0_N f dP$ a good approximation for $\delta^0_N$.

Let $n$ be the number of particles in the "simulation gas". Now let us try to find an initial state $\delta^0_n$ for these particles, such that the distance

$$\rho(\delta^0_n(t), \bar{\mu}_t)$$

of the state of the simulated $n$-particle system at time $t$ to the solution of the Vlasov equation at the same time is as small as possible.

It should be clear that the only possibility to be successful is in constructing $\delta^0_n$ for given $\bar{\rho}$. Then $\delta^0_n(t)$ is given by solving the Newtonian system (3), which can be done at least numerically in a satisfying manner, if $n$ is not too large. But it is again necessary to smooth the interaction forces or, equivalently, to "smear out" the particles. This is done by PIC - the particles are
smeared out over cells.

We want to get some information about how the complexity of the method increases if we increase the dimension $k$; $k=3$ is the normal case of 3 space and 3 velocity variables. The interaction force is then given by

$$G(x, y) = -\gamma \frac{x-y}{||x-y||^k}, \quad k=1,2,3.$$  

The steps of PIC are:

**Step 1:** Choose $\omega_\delta$ such that $\rho(\delta, n)$ is as small as possible

("as small as possible" means: as small as you can make it):

$$\omega_\delta = \{ (x_1, v_1), \ldots, (x_n, v_n) \}.$$  

**Step 2:** Instead of $\omega_\delta$ given in lecture 1 we choose a less smooth but simpler mollifier

$$\omega_\delta(x) = \begin{cases} \frac{1}{\gamma_k} & \text{for } ||x|| \leq \delta \\ \gamma_k & \text{otherwise} \end{cases},$$

where $\gamma_k$ is the volume of the $k$-dimensional unit ball, $\gamma_1 = 2$, $\gamma_2 = \pi$, $\gamma_3 = \frac{4\pi}{3}$.

We use this $\omega_\delta$ in order to smear out the particles over balls of radius $\delta$ in the x-space (i.e. over "cells"); therefore we substitute the spatial distribution

$$\frac{1}{n} \sum_{j=1}^{n} x_j$$

of the $n$-particle system by a distribution with the spatial density

$$\rho_n(x) := \frac{1}{n} \sum_{j=1}^{n} \omega_\delta(x-x_j) = \int \omega_\delta(x-z) d\omega_n(z,v)$$

of $\mathbb{R}^k$.

Then

$$\int_{\mathbb{R}^k} G(x, y) \rho_n(y) dy = \int_{\mathbb{R}^k} G(x, y) \left( \int \omega_\delta(y-z) d\omega_n(z,v) \right) dy$$
\[
\int \left( \int_{\mathbb{R}^k} G(x,y) \omega_\delta(y-z) dy \right) d\delta_n(z,v) \\
\int_{\mathbb{R}^k} G_\delta(x,z) d\delta_n(z,v) 
\]
so that this procedure is equivalent to our former modification, where we substitute \(G\) by \(G_\delta\).

**Remark:** Our procedure consists in smearing out a particle over a \(\delta\)-ball centered at the particle. The normal PIC uses fixed cells not depending on the positions of the particles, but adds afterwards a so-called area weighting, which gives at least for \(k=1\) exactly the same values of \(\rho_n\). For \(k > 1\) the differences are not important and can be avoided by using another \(\omega_\delta\).

**Step 3:** Calculate
\[
\rho_n(x) = E_n(0,x) = \int G(x,y) \rho_n(y) dy
\]
for \(x = x_j^0, j=1,\ldots,n\). Since \(\rho_n\) is a step function, the integration can be done explicitly; one only has to evaluate \(n\) values of an explicit function.

**Step 4:** Propagate the particles for a time step \(\Delta t > 0\) by
\[
\hat{v}_i(\Delta t) = \hat{v}_i + \Delta t E_n(0,\hat{x}_i) \\
\hat{x}_i(\Delta t) = \hat{x}_i + \Delta t \hat{v}_i(\Delta t)
\]

(33)

This provides the first step of a numerical integration of the characteristic equations
\[
\dot{x} = v \\
\dot{v} = E[\delta_n(\cdot)](t,x).
\]

\((\hat{x}_j(\Delta t), \hat{x}_j(\Delta t))\) is an approximation for \(T_{\Delta t,0}[\omega_n(\cdot)]^{\rho}_P\).

Choosing the symmetric difference scheme (33) has some advantages. The mapping
\[
(\hat{x}_1^0, \hat{v}_1^0) \rightarrow (\hat{x}_1(\Delta t), \hat{v}(\Delta t)) = P_1(\Delta t)
\]
has some of the properties \(T_{\Delta t,0}|_U\) has: It is measure preserving and bijective.
Step 5: Repeat the process with \((\hat{P}_1(\Delta t), \ldots, \hat{P}_n(\Delta t))\) instead of 
\((\hat{P}_1, \ldots, \hat{P}_n)\) in order to get \(\rho_n(\Delta t, x)\), \(E_n(\Delta t, x)\) and finally 
\(\hat{P}_1(2\Delta t), \ldots, \hat{P}_n(2\Delta t)\) and so on.

**Remark:** As the numerical method is uniformly convergent for \(\Delta t \to 0\), we have 
\[ ||P_1(m\Delta t) - \hat{P}_i(m\Delta t)|| \leq \varepsilon \]  
for \(0 \leq m\Delta t \leq T\), if \(\Delta t\) is small enough. Hence

\[
\rho(\delta_{\omega_n}(t), \delta_{\tilde{\omega}_n}(t)) = \sup_{\varphi \in \mathcal{D}} \left| \int \varphi \, d\delta_{\omega_n}(t) - \int \varphi \, d\delta_{\tilde{\omega}_n}(t) \right|
\]

\[
\leq \sup_{\varphi \in \mathcal{D}} \frac{1}{n} \sum_{j=1}^{n} |\varphi(P_1(t)) - \varphi(\hat{P}_i(t))| \leq \max_{i=1, \ldots, n} ||P_1(t) - \hat{P}_i(t)|| \leq \varepsilon
\]

for \(t = m\Delta t\), \(\Delta t\) small enough.

According to theorem 1
\[
\rho(\mu_t, \delta_{\omega_n}(t)) \leq e^{Ct}\rho(\mu, \delta_{\omega_n})
\]

therefore
\[
\rho(\mu_t, \delta_{\omega_n}(t)) \leq \rho(\mu_t, \delta_{\omega_n}(t)) + \rho(\delta_{\omega_n}(t), \delta_{\tilde{\omega}_n}(t)) \leq \varepsilon + e^{Ct}\rho(\mu, \delta_{\omega_n})
\]

Consequently, PIC converges in the sense that for given \(\varepsilon > 0\), \(T > 0\) one can choose \(\Delta t\) small enough and \(n\) large enough such that
\[
\rho(\mu_t, \delta_{\omega_n}(t)) < \varepsilon \quad \text{for } t = m\Delta t, \ 0 \leq m\Delta t \leq T.
\]

This entails that the numerically calculated electric field \(\tilde{\omega}_n\) approximates the real electric field \(E\) uniformly, i.e.
\[
||E_n(m\Delta t, \cdot) - E(m\Delta t, \cdot)||_0 < \varepsilon \quad \text{for } 0 \leq m\Delta t \leq T, \ \Delta t \text{ sufficiently small.}
\]

Looking a bit more carefully, how the constant \(C = K + L\) in the preceding estimate depends on \(\delta\) and the dimension \(k\), one gets
\[
\rho(\mu_t, \delta_{\omega_n}(t)) \leq e^{C(k, \delta)t}\rho(\mu, \delta_{\omega_n})
\]

with
\[
C(k, \delta) = \sqrt{2}(1 + \frac{\sqrt{k}}{\delta}(1 - \frac{\sqrt{2}}{\delta(k-1)})).
\]
If $\delta$ is chosen near to 1 (i.e. in physical dimensions: approximately equal to the so-called Debye length), then $C(k, \delta)$ is of order $\sqrt{k}$.

The only thing which remains to be done and which is of big practical importance is to find an appropriate $\omega_n^0$ for given $\bar{\nu} = \int f \, d\nu$. For the special case $\bar{f} = \chi_E$, where $E$ is the unit cube in $\mathbb{R}^{2k}$, $E = \{ p \in \mathbb{R}^{2k} | 0 < p_i < 1, i=1, \ldots, 2k \}$ and $\chi_E$ is the characteristic function of $E$, there are some results available. Therefore we reduce the general case to the special one.

So we will discuss a method to construct a "good" (not a best) $\omega_n^0$ for given $\bar{\nu} = \int f \, d\nu$. For the special case $\bar{f} = \chi_E$, where $E$ is the unit cube in $\mathbb{R}^{2k}$, $E = \{ p \in \mathbb{R}^{2k} | 0 < p_i < 1, i=1, \ldots, 2k \}$ and $\chi_E$ is the characteristic function of $E$, there are some results available. Therefore we reduce the general case to the special one.

We assume, that there exists a convex domain $B$ in $\mathbb{R}^{2k}$ such that $\bar{f}(P) > 0$ for $P \in B$, $\bar{f}(P) = 0$ for $P \notin B$. Then one is able to construct a mapping $T : B \rightarrow E$, which has the following properties:

1. $T$ is differentiable and bijective, and its Jacobian is $\det J_T(P) = \frac{\partial \bar{f}}{\partial \bar{f}}(P)$, $P \in B$.

Then $\bar{\nu} = \nu_E \circ T$, where $\nu_E = \int \chi_E \, d\nu$ is the uniform distribution in $E$:

$$\bar{\nu}(M) = \int \chi_E \, d\nu = \int \chi_E \, d\nu = \int \chi_E \, d\nu = \int \chi_E \, d\nu = \nu_E(T(M))$$

for arbitrary $M$.

The construction of $T$ is given in a paper by Hlawka and Mück in 1972. It is simple when $f$ factorises, i.e.

$$\bar{f}(P) = \bar{f}_1(P_1) \cdots \bar{f}_{2k}(P_{2k})$$

$p_i = x_i$ and $p_{k+i} = y_i$ for $i=1, \ldots, k$.

Then

$$T(P) := T_1(P_1) = \int \bar{f}_1(\ell) \, d\nu_i, \quad i=1, \ldots, 2k, \quad P \in B.$$ 

If now $\hat{\omega}_n^0 = \{ \hat{P}_1, \ldots, \hat{P}_n \}$ is a good approximation for $\nu_E$, then $\omega_n^0 := \{ T^{-1} \hat{P}_1, \ldots, T^{-1} \hat{P}_n \}$ is a good approximation for $\bar{\nu}$. If $T^{-1}$ is Lipschitz continuous with a Lipschitz constant $\lambda$, then

$$\nu(\delta, \omega_n^0) \leq \lambda \nu(\delta, \omega_n^0).$$

$T^{-1}$ is relatively easy to calculate in the special case mentioned.
above. The discrepancy, defined in (6) is also a metric which measures the distance of $\delta_0$ to $\mu$. For the purposes discussed here it is easier to handle. For example, for a factorising $f$, a set $R \in \mathcal{R}$ is transformed by $T$ into a set of the same kind whose corner $Q$ is in $E$. It follows that for these kind of initial conditions even the quality

$$D(\delta_0, \mu) = D(\delta_n, \mu_E)$$

holds.

Therefore, it remains to construct $\delta_n$. We have to point out, that this problem cannot be solved in a nice way by using a random generator: The only property $\delta_n$ has to have is, that the discrepancy $D(\delta_n, \mu_E)$ is small, therefore things like correlations are irrelevant. $\delta_n$ might be distributed very regularly - this is what physicists call a "quiet start".

There is a method proposed by Niedereiter how to calculate $D(\delta_n, \mu_E)$ without taking the l.u.b. over all $R \in \mathcal{R}$; a finite number of property selected $R$ is enough.

Just to give you an example how real calculations are done, we consider the one dimensional case $k=1$. For $n$ we choose only the Fibonacci numbers $n=a_k$, $k \in \mathbb{N}$ with $a_0 = a_1 = 1$, $a_{k+1} = a_k + a_{k-1}$.

Then we choose $\{\tilde{P}_1, \ldots, \tilde{P}_n\}$ with $\tilde{P}_i = (x_i, v_i)$ in the following way:

$$x_i = \frac{2i-1}{2a_k}, \quad v_i = \frac{2(i-1)a_{k-1}+1}{2a_k}, \quad i = 1, \ldots, a_k = n,$$

where $|\cdot|$ denotes the fractional part of the positive real number $\cdot$.

One obtains the following values for $D(\delta_n, \mu_E)$:

<table>
<thead>
<tr>
<th>$k$</th>
<th>$a_k = n$</th>
<th>$D(\delta_n, \mu_E)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>144</td>
<td>$1.5 \cdot 10^{-2}$</td>
</tr>
<tr>
<td>14</td>
<td>377</td>
<td>$7.6 \cdot 10^{-3}$</td>
</tr>
<tr>
<td>16</td>
<td>987</td>
<td>$3.3 \cdot 10^{-3}$</td>
</tr>
<tr>
<td>18</td>
<td>2584</td>
<td>$1.4 \cdot 10^{-3}$</td>
</tr>
<tr>
<td>20</td>
<td>6765</td>
<td>$5.6 \cdot 10^{-4}$</td>
</tr>
</tbody>
</table>
For 6765 points, generated by the IBM-random-generator, the discrepancy is $1.4 \cdot 10^{-2}$; that means, that you need only 144 points with the construction given above to obtain a similar result. The computing time however differs by a factor 47.

In the table given above one realizes that the convergence of $D(\delta_n, n) = D_n$ to zero is rather slow. In fact it has been shown by number theorists, that there exists a constant $C_k$, depending only on the dimension, such that

$$D_n \sim \frac{C_k}{n} \left( \frac{k-1}{2} \right) \left( \ln n \right)$$

So, one cannot expect a very quick convergence of the method. Nevertheless, it is better than most of the other methods used in praxis - and its convergence is proved!

6. Stationary Solutions

Not very much is known about stationary (i.e. time independent) solutions. The only exception is the one-dimensional case, where all solutions can be explicitly constructed. These solutions, discovered in 1957, are the so-called "Bernstein-Green-Kruskal"-modes (BGK-modes).

The problem is to construct all solutions of the system

\begin{align}
(34a) & \quad v \frac{\partial f}{\partial x} + E(x) \frac{\partial f}{\partial v} = 0 \\
(34b) & \quad v \frac{\partial f}{\partial x} - E(x) \frac{\partial f}{\partial v} = 0 \\
(35) & \quad c_+ \int_{-\infty}^{+\infty} f_-(x,v) \, dx - c_- \int_{-\infty}^{+\infty} f_+(x,v) \, dv = E'(x),
\end{align}

where $c_-$ and $c_+$ are some positive constants. $f_-$, $f_+$ are the distribution functions of the electrons and the ions respectively. We consider here a two-component gas, because in this case the solutions become even simpler.

By solving (35) together with some boundary values for $E$ and substituting the solution into (34) one realizes that the problem is again nonlinear.
However, the main idea is to make the problem linear by prescribing appropriate data of $f$. If we look for solutions of (34), (35) with

$$
\rho(x) := c_- \int_{-\infty}^{x} f_-(x,v) dv - c_+ \int_{-\infty}^{x} f_+(x,v) dx
$$

given, then $E'(x)$ is known from the data, $E$ is - up to a boundary condition - a known function and we have to solve the linear equation (34) with the rather unusual condition (36).

For a given $E$, let us consider (34a). As $f_-$ depends only on two variables $x$ and $v$, we know that a function $f_-$ is a solution of (34a) if and only if it depends only on the Hamiltonian

$$
H(x,v) = v^2 - 2U(x)
$$

where $U$ is an arbitrary integral of $E$

$$(38a) \quad f_-(x,v) = \phi_-(v^2 - 2U(x)).$$

Similarly $f_+$ has to be of the form

$$(38b) \quad f_+(x,v) = \phi_+(v^2 + 2U(x)).$$

The figure on the following page gives you a typical picture for the level curves of $f_+$, $f_-$ for a given $U$. To different branches of such a level curve one might assign different values of the functions $f_\pm$.

These level curves for $f_+$ degenerate to a single point at $x_1$, where $U$ has a local minimum, if we choose $c = 2U(x_1)$. For $c < 2U(x_1)$ the level curve is an empty set.

The level curves have an intersection with the $x$-axis, if $\frac{c}{2}$ is contained in the range of $U$; at these intersection points, the level curves are orthogonal to the $x$-axis.

The level curves for $f_-$ behave somewhat antisymmetric. They degenerate at maximum points $x_0$ of $U$, do not exist for $c > 2U(x_0)$ and intersect with the $x$-axis, if $\frac{c}{2}$ is contained in the range of $-U$.

We restrict our considerations for a moment to an interval of strict monotonicity of $U$, say $[x_0, x_1]$ and choose an arbitrary $x$ in $(x_0, x_1)$.

Every point $(x,v)$ in the strip $[x_0, x_1] \times \mathbb{R}$ lies on a level curve of $f_+$, which passes $x = \xi$. This is not true for the level curves of $f_+$. 
The potential

\[ v^2 + 2U(x) = \text{const} \]

\[ v^2 - 2U(x) = \text{const} \]

characteristics of \( f_+ \)

characteristics of \( f_- \)
The level curve passing \((t, 0)\) is given by
\[
v^2 + 2(U(x) - U(t)) = 0.
\]
Therefore points \((x, v) \in [t, x_1] \times \mathbb{R} \) with
\[
|v| < \sqrt{2(U(t) - U(x))}
\]
are not reached by curves passing \((t, 0)\).

If, in addition to \(p\) according to (36), we prescribe the boundary values
\[
(39) \quad f_+(t, v) = \varphi_+(v), \quad f_-(t, v) = \varphi_-(v),
\]
then \(f_-\) is completely determined in \([t, x_1] \times \mathbb{R}\); \(f_+\) is determined only for \((x, v)\) with \(t \leq x \leq x_1\), \(|v| \geq \sqrt{2(U(t) - U(x))}\).

Therefore \(\int_{-\infty}^{+\infty} f_-(x, v) dv\) is determined by \(\varphi_-\), \(\int_{-\infty}^{+\infty} f_+(x, v) dv\) by \(\varphi_+\).

In order to satisfy (36), we have to solve the equation
\[
\frac{\int f_+(x, v) dv}{+\sqrt{2(U(t) - U(x))}} = -\frac{\varphi_+(v)}{c_+} - \frac{\varphi_-}{c_+} \int f_-(x, v) dv - \frac{\varphi_+(v)}{+\sqrt{2(U(t) - U(x))}}.
\]

\(h\) is known in \([t, x_1]\); using (38b), we get
\[
\sqrt{2(U(t) - U(x))} = 2 \int_0^x \varphi_+(v^2 + 2U(x)) dv = h(x).
\]

With \(v^2 + 2U(x) = t\), we find
\[
\frac{2U(t) \int f_+(t) \frac{dt}{\sqrt{t - 2U(x)}}}{2U(x)} = h(x).
\]

\(U\) is strictly monotone in \(x\); so \(2U\) has an inverse function \(W\) and we obtain
\[
\frac{2U(t)}{y} \int y \frac{dt}{\sqrt{t - y}} = h(W(y)).
\]

This is Abel's integral equation, which has the unique solution
\[
(40) \quad \varphi_+(z) = \frac{1}{n} \frac{d}{dz} \int_2^{2U(t)} \frac{h(W(t))}{\sqrt{t - z}} \, dt, \quad 2U(x) \leq z \leq 2U(t).
\]

We do not want to work out all the details. However, we note that \(f_+(x, v) = \varphi_+(v^2 + 2U(x))\) is now completely known:
For $|v| > \sqrt{2(U(\xi)-U(x))}$ it is given by $\psi_+$, for $|v| < \sqrt{2(U(\xi)-U(x))}$ it is determined via (40).

Consequently $f_+$, $f_-$ are determined in $[\xi, x_1] \times \mathbb{R}$ by (36), (39).

We can continue the procedure, e.g., to the right of $x_1$.

$f_+(x_1, v)$, $f_-(x_1, v)$ are known. Therefore $f_+(x, v)$ is determined for $(x, v) \in [x_1, x_2] \times \mathbb{R}$, where $x_2$ is the point of the next maximum. In that strip $f_-$ can be constructed by solving Abel's integral equation. In that way, we get the solution everywhere.

We have to mention, that we are looking for what is called a "mild" solution of (34), i.e. a solution, which is constant along the characteristics (the level curves) and continuous. We get the following

**Theorem 7**: Suppose $E \in C^2(\mathbb{R})$ such that $E''(x) = O(E(x))$ for $x \to \pm\infty$ for any $\eta$ with $E(\eta) = 0$, and assume $\psi_+ \in C_0 \cap L_1$ with the following properties:

(a) If $\Lambda_+(\xi) = \sup(U(x)-U(\xi))$, $\Lambda_-(\xi) = -\inf(U(x)-U(\xi))$, then $\psi_+$ is even and Hölder continuous for $\frac{\psi_2}{2} \cdot \Lambda_+(\xi)$

(b) $E'(\xi) = c_- \int_{-\infty}^{\xi} \psi_- dv + c_+ \int_{\xi}^{\infty} \psi_+ dv$

Then the system (34), (35) has a unique mild solution, where $E$ is the given function and $f_+(\xi, v) = \psi_+(v)$.

**Remark**: The assumptions on $E$ and $\psi_+$ are natural and necessary to get a mild solution. This solution can be explicitly constructed and is called a BGK-mode.

There is only one weak point: There are no simple conditions for $E$ (or $\rho$ respectively) and $\psi_+$, such that $f_+$ is everywhere non-negative. So one really has to calculate the solutions to be sure that they are physically relevant.

I want to show you another derivation of the solution, which in my opinion is nice and shows something about the increase of complexity in higher dimensions.
In order to simplify the subject we consider again the interval \([x_0, x_1]\), where \(U\) is strictly monotonically decreasing, and let \(\ell \in [x_0, x_1]\).

Again we assume, that \(E\) and \(f_\pm\) are already known in \([\ell, x_1] \times \mathbb{R}\), so we have to solve

\[
\frac{\partial f_\pm}{\partial x} - E \frac{\partial f_\pm}{\partial y} = 0
\]

with \(f_\pm(\ell, v) = \varphi_\pm(v)\) and \(\int_{-\infty}^{\infty} f_\pm(x, v) dv = \rho_\pm(x)\) given.

Let us forget about characteristics but make a Fourier transform of the equation with respect to \(v\):

With \(u(x, y) := \int_{-\infty}^{\infty} e^{-iyv} f(x, v) dv\), we get formally

\[
iu_{xy} - Eiyu = 0
\]

with \(u(\ell, y) = \hat{\varphi}_\pm(y) = \int_{-\infty}^{\infty} e^{-iyv} \varphi_\pm(v) dv\) and \(u(x, 0) = \varphi_\pm(x)\).

We end up with a characteristic "initial value" problem for a hyperbolic equation:

\[
(41) \quad u_{xy} - E(x)y u = 0, \quad u(\ell, y) = \varphi_\pm(y), \quad u(x, 0) = \varphi_\pm(x)
\]

There is a simple trick to solve this equation, a trick, which seems not to be well-known: If you have to solve \(u_{xy} + f(x) \cdot g(y) u = 0\), substitute

\[
u(x, y) = U(F(x), G(y)),
\]

where \(F, G\) are integrals of \(f, g\) respectively. Then you get

\[
U_{\ell, n} + U = 0
\]

and the Riemann function for that equation is just

\[
G(\ell, n; \ell', n') = I_0 \left(2\sqrt{(\ell - \ell')(n - n')}\right).
\]

Therefore, you get as a Riemann function for the original problem

\[
(42) \quad G(x, y; x', y') = I_0 \left(2\sqrt{(U(x) - U(x'))(\frac{Y_1^2}{2} - \frac{Y_2^2}{2})}\right)
\]

where \(I_0\) is the zeroth order Bessel function of first kind. \(G\) is always real, even if the argument is complex.

The Riemann function \(G\) is defined to be a solution of \(u_{xy} - E(x)y u = 0\) with respect to the variables \(x, y\) and satisfies the boundary
conditions
\[ G(x', y, x', y') = G(x, y', x', y') = 1 \quad \text{for all } x, y, x', y'. \]

Using (42), one gets the solution of the "characteristic" boundary value problem (41) as
\[
\begin{align*}
  u(x, y) &= d \int_0^x I_0(\sqrt{2(U(t)-U(x))}y) \rho_+(t) \, dt \\
  &\quad + \int_0^y I_0(\sqrt{2(U(t)-U(x))}(y^2-t^2)) \rho_+(t) \, dt
\end{align*}
\]
with \( d := u(\xi, 0) = \hat{\varphi}_+(0) = \varphi_+(\xi) \).

It is possible to calculate explicitly the inverse Fourier transform of \( u \) in order to get \( f_+ \). For example, the first term yields
\[
\frac{1}{\sqrt{2(U(\xi)-U(x)) - v^2}} \quad \text{if } 2(U(\xi)-U(x)) - v^2 > 0 \text{ and 0 otherwise.}
\]

Note the Hamiltonian. This approach yields exactly the same explicit solution of the problem as the method using Abel's integral equation.

What about higher dimensions?
If one is interested in a very special kind of solutions — those depending only on the Hamiltonian, i.e. for example
\[
f_-(x, v) = \varphi_-(\|v\|^2 - 2U(x))
\]
everything works like in the one dimensional case; instead of Abel's integral equation, one gets an equation of the form
\[
q(z) = \int_0^1 k(t)(t-y) \frac{z-2}{2} \, dt, \text{ where } k=1,2,3
\]
is the dimension.

This equation can be easily solved by using fractional derivatives of \( q \) (for \( k=2 \) there is nothing to solve!) and one gets again explicit solutions, the so-called "more-dimensional BCG-modes".

But — in contrast to the one-dimensional case — these solutions are by far not all solutions of the problem — besides the energy, there are more integrals for the Newtonian system, which cannot be given explicitly. For example Horst remarked, that if \( k=2 \) and \( \hat{\varphi} \) is a stationary solution for the stellardynamic case (for example a two-
dimensional BGK-mode), then
\[ \phi(x,v) = \hat{\phi}(x,v) (1 + \gamma(x_1 v_2 - x_2 v_1)) \]
is also a stationary solution, if \( \gamma: \mathbb{R} \to [-1,1] \) is an odd function. If one tries to play the Fourier transform trick, one gets for \( k = 2 \)
\[ u_{x_1 y_1} + u_{x_2 y_2} + \langle E(x_1, x_2) \rangle u = 0. \]
This may be transformed to
\[ \Lambda_{\xi} \tilde{u} - \Lambda_{\eta} \tilde{u} + \langle E(\xi+\eta), \xi-\eta \rangle \tilde{u} = 0, \quad \xi := \frac{x+y}{2}, \quad \eta := \frac{x-y}{2}. \]
The difference of the two Laplacians show that this is a so-called "ultrahyperbolic" equation; not very much is known about that kind of partial differential equations. In particular, it is hard to decide, what kind of boundary value problems are properly posed - remember, that we need \( u(x,0) = u(\xi, \xi) \) as data to linearize the problem. The problem of determining all stationary solutions in more than one dimension stays widely open.

Final remarks: Almost all of the material presented in these lectures is mainly of mathematical interest. Now questions of real physical interest arise. i.e.:

1) What is the qualitative character of a global solution? How does the system behave in a long run of time? When is it periodic?

2) Which of the stationary solutions are stable, which are not?

The second question can only be asked with respect to the BGK-modes. A lot of results concerning the problem of linear stability are available, most of them not really rigorous, but they can eventually be made rigorous with some effort. Nothing rigorous is known on non-linear stability as far as I know. But this should be a field of great interest with respect to physical applications, especially since BGK-modes have really been observed in a plasma a few years ago.

Concerning the first question there is almost nothing known today. The only exception is an example given by Kurth, which I want to put on the end of these lectures. We consider the stellardynamic case and are interested in a solution \( f(t, \cdot) \), whose spatial density \( \rho(t, \cdot) \)
is constant in a certain ball whose diameter \( r = r(t) \) depends on time
\[
\rho(t,x) = \frac{1}{4\pi} r^{-3}(t) \quad \text{if} \quad ||x|| < r(t)
\]
and
\[
\rho(t,x) = 0 \quad \text{otherwise}.
\]

Choose \( r(t) \) as a solution of
\[
r^3 + r = 1, \ r(0) = 1, \ \dot{r}(0) = H = \text{const}.
\]

This solution can be calculated, depending on \( H \). Then define
\[
f(t,x,v) = \begin{cases} 
\frac{3^3}{2^3} \left[ 1 - \frac{||x||^2}{r^2(t)} \right]^{-\frac{1}{2}} \left[ ||r(t)v - r(t)x||^2 + ||x||^2 \right]^{-\frac{1}{2}} & \text{if} \quad ||x|| < r(t) \\
0 & \text{otherwise}
\end{cases}
\]

Then \( f \) is a solution of the Vlasov-equation, whose spatial density is of the desired form. \( H \) might be interpreted as the (dimensionless) Hubble constant. As you may realize there is a lot of astrophysical experience needed to find such a solution. Its behaviour strongly depends on \( H \): For \( H < 1 \) it behaves periodically, for \( H > 1 \) the density \( \rho \) goes to zero with respect to the \( L^\infty(\mathbb{R}^3) \)-Norm.

One might realize by considering this example how complicated the answers for example on questions of the stability or instability of solutions might be.

Nevertheless, working in the field of the Vlasov equation one follows somehow the interest and the efforts of most of the great mathematicians of the 17th and 18th century. Most of the work they did were concerned with astronomy, the explanation of the behaviour of the universe (compare for example the highly interesting book "Mathematics, The Loss of Certainty" by Morris Kline, New York 1980). Therefore, the research on the Vlasov equation could be a challenge even for modern mathematicians.

Acknowledgement. Most of the own research work presented in these lectures was done during the last ten years mainly in collaboration with some of my colleagues and students. I want to mention here H. von der Bank, J. Wick, R. Illner and K.H. Petry. The final
version of the lectures were worked out during my one month stay at the Centre du recherche pure et appliquée at the Université de Montréal and I want to thank Prof. Anatol Joffe giving me the opportunity to work in the inspiring atmosphere of the centre and especially Prof. Marvin Shinbrot for many fruitful and inspiring discussions.
